This manual collects all of Pure’s online documentation: *The Pure Manual* which covers the Pure language and the operation of the Pure interpreter; the *Pure Library Manual* which describes the standard library modules included in the distribution of the Pure interpreter; all available documentation for the various addon modules which can be downloaded as separate packages from the Pure website; and an appendix with installation instructions.

Most of the Pure documentation is distributed under the GNU Free Documentation License. The authors of the current edition are listed below. (This just lists the primary section authors in alphabetical order; please check the different parts of this manual for additional authorship and licensing information.)

- Albert Gräf (*The Pure Manual; Pure Library Manual; various addon manuals*)
- Rob Hubbard (*Pure-Rational - Rational number library for the Pure programming language*)
- Kay-Uwe Kirstein (*Gnuplot bindings*)
- Eddie Rucker (*Pure-CSV - Comma Separated Value Interface for the Pure Programming Language; pure-gsl - GNU Scientific Library Interface for Pure*)
- Jiri Spitz (*Pure-GLPK - GLPK interface for the Pure programming language*)
- Peter Summerland (*Pure-Sql3, pure-stlmap, pure-stlvec*)

The Pure programming system is free and open source software. The interpreter runtime, the standard library and most of the addon modules are distributed under the GNU Lesser General Public License or the 3-clause BSD License which allow for commercial applications. Some parts of the system also use the GNU General Public License (typically because they interface to other GPL’ed software such as Gnumeric, GSL and Octave). Details about authorship and license conditions can be found in the sources or in the various manual sections.

For more information, discussions, feedback, questions, suggestions etc. please see:

- Pure website: https://agraef.github.io/pure-lang/
- Pure mailing list: http://groups.google.com/group/pure-lang
Chapter 1

The Pure Manual

Version 0.68, May 13, 2020
Albert Gräf <aggraef@gmail.com>

Copyright (c) 2009-2018 by Albert Gräf. This document is available under the GNU Free
Documentation License. Also see the Copying section for licensing information of the soft-
ware.

This manual describes the Pure programming language and how to invoke the Pure inter-
preter program. To read the manual inside the interpreter, just type help at the command
prompt. See the Online Help section for details.

There is a companion to this manual, the Pure Library Manual which contains the description
of the standard library operations. More information about Pure and the latest sources can
be found under the following URLs:

- Pure website: https://agraef.github.io/pure-lang/
- Pure mailing list: http://groups.google.com/group/pure-lang

Information about how to install Pure can be found in the document Installing Pure (and
LLVM).

1.1 Introduction

Pure is a functional programming language based on term rewriting. This means that all
your programs are essentially just collections of symbolic equations which the interpreter
uses to reduce expressions to their simplest (“normal”) form. This makes for a rather power-
ful and flexible programming model featuring dynamic typing and general polymorphism.
In addition, Pure programs are compiled to efficient native code on the fly, using the LLVM
compiler framework, so programs are executed reasonably fast and interfacing to C is very
easy. If you have the necessary 3rd party compilers installed then you can even inline func-
tions written in C and a number of other languages and call them just like any other Pure
function. The ease with which you can interface to 3rd party software makes Pure useful for
a wide range of applications from symbolic algebra and scientific programming to database, web and multimedia applications.

The Pure language is implemented by the Pure interpreter program. Just like other programming language interpreters, the Pure interpreter provides an interactive environment in which you can type definitions and expressions, which are executed as you type them at the interpreter’s command prompt. However, despite its name the Pure interpreter never really “interprets” any Pure code. Rather, it acts as a frontend to the Pure compiler, which takes care of incrementally compiling Pure code to native (machine) code. This has the benefit that the compiled code runs much faster than the usual kinds of “bytecode” that you find in traditional programming language interpreters.

You can use the interpreter interactively as a sophisticated kind of “desktop calculator” program. Simply run the program from the shell as follows:

```
$ pure
```

```
_ _ \ | | --| _ _\ Pure 0.68 (x86_64-unknown-linux-gnu)
| | | | | | __/ Copyright (c) 2008-2018 by Albert Graef
\__/ \__,_|_\ ___| (Type 'help' for help, 'help copying'

Loaded prelude from /usr/lib/pure/prelude.pure.

>

The interpreter prints its sign-on message and leaves you at its “>” command prompt, where you can start typing definitions and expressions to be evaluated:

```
> 17/12+23;
24.4166666666667
> fact n = if n>0 then n*fact (n-1) else 1;
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

Typing the quit command or the end-of-file character (Ctrl-d on Unix systems) at the beginning of the command line exits the interpreter and takes you back to the shell.

The interpreter can actually be invoked in a number of different ways. Instead of typing definitions and evaluating expressions in an interactive fashion as shown above, you can also put the same code in an (ASCII or UTF-8) text file called a Pure program or script which can then be executed by the interpreter in “batch mode”, or compiled to a standalone executable which can be run directly from the command line. As an aid for writing script files, a bunch of syntax highlighting files and programming modes for various popular text editors are included in the Pure sources.

More information about invoking the Pure interpreter can be found in the Invoking Pure section below. This is followed by a description of the Pure language in Pure Overview and subsequent sections, including an extensive Examples section which can serve as a mini-tutorial on Pure. The interactive facilities of the Pure interpreter are discussed in the Interactive Usage section, while the Batch Compilation section explains how to translate Pure programs to native executables and a number of other object file formats. The Caveats and
Notes section discusses useful tips and tricks, as well as various pitfalls and how to avoid them. The manual concludes with some authorship and licensing information and pointers to related software.

1.1.1 Further Reading

This manual is not intended as a general introduction to functional programming, so at least some familiarity with this programming style is assumed. If Pure is your first functional language then you might want to look at the Functional Programming wikipedia article to see what it is all about and find pointers to current literature on the subject. In any case we hope that you’ll find Pure helpful in exploring functional programming, as it is fairly easy to learn but a very powerful language.

As already mentioned, Pure uses term rewriting as its underlying computational model, which goes well beyond functional programming in some ways. Term rewriting has long been used in computer algebra systems, and Michael O’Donnell pioneered its use as a programming language already in the 1980s. But until recently implementations have not really been efficient enough to be useful as general-purpose programming languages; Pure strives to change that. A good introduction to the theory of the term rewriting calculus and its applications is the book by Baader and Nipkow.

1.1.2 Typographical Conventions

Program examples are always set in typewriter font. Here’s how a typical code sample may look like:

```plaintext
fact n = if n>0 then n*fact(n-1) else 1;
```

These can either be saved to a file and then loaded into the interpreter, or you can also just type them directly in the interpreter. If some lines start with the interpreter prompt “> ”, this indicates an example interaction with the interpreter. Everything following the prompt (excluding the “> ” itself) is meant to be typed exactly as written. Lines lacking the “> ” prefix show results printed by the interpreter. Example:

```
> fact n = if n>0 then n*fact(n-1) else 1;
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

Similarly, lines starting with the “$ ” prompt indicate shell interactions. For instance,

```
$ pure
```

indicates that you should type the command pure on your system’s command line.

The grammar notation in this manual uses an extended form of BNF (Backus-Naur form), which looks as follows:

```plaintext
expression ::= "{" expr_list ";" expr_list* [";"] """
expr_list ::= expression (',' expression)*
```
Parentheses are used to group syntactical elements, while brackets denote optional elements. We also use the regular expression operators * and + to denote repetitions (as usual, * denotes zero or more, + one or more repetitions of the preceding element). Terminals (literal elements such as keywords and delimiters) are enclosed in double or single quotes.

These EBNF rules are used for both lexical and syntactical elements, but note that the former are concerned with entities formed from single characters and thus tokens are meant to be typed exactly as written, whereas the latter deal with larger syntactical structures where whitespace between tokens is generally insignificant.

### 1.2 Invoking Pure

The Pure interpreter can be invoked from the shell in one of two different ways:

```
pure [options ...] [-x] script [args ...]
pure [options ...] [-b|-c|-i] [script ...] [-- args ...]
```

Use `pure -h` to get help about the command line options. Just the `pure` command without any command line parameters invokes the interpreter in **interactive mode**, see Running **Interactive** below for details.

The first form above is used if the interpreter is invoked on exactly one script file, which is loaded and executed, after which the interpreter exits. Any arguments following the script name are *not* processed by the interpreter, but are passed to the executing script by means of the `argv` variable. This is also known as **script mode**, and is commonly used if a script is to be run as a standalone program. Script mode can also be indicated explicitly with the `-x` option, but this is optional unless you want to combine it with one of the `-b`, `-c` and `-i` options discussed below. If the `-x` option is present, it must be followed by the name of a script to be executed. Also note that in script mode, all interpreter options need to be specified before the script name; all remaining arguments (including options) are simply passed to the executing script.

The second form is used if there may be any number of scripts which are to be executed in **batch mode** (`-b`, `-c`) or **interactive mode** (`-i`), respectively. In this case all options on the command line will be processed by the interpreter, up to the `--` option (if any), which stops option processing and indicates that the remaining arguments should be passed in the `argv` variable. Any non-option arguments (before the `--` option, if any) are interpreted as scripts which should be loaded by the interpreter. If no scripts are specified, or if the `-i` option is present, the interpreter starts in interactive mode (after loading the given scripts, if any). Otherwise, if one of the `-b` and `-c` options is specified, the given scripts are run in batch mode, after which the interpreter exits. (In the case of `-c`, the interpreter then also dumps the program as a native executable, performing **batch compilation**, see **Compiling Scripts** below.)

Batch mode is also entered if the interpreter is invoked with one of the `--check`, `--ctags` and `--etags` options. However, in this case the given scripts are not executed at all, but only parsed in order to check them for syntactic validity, or to produce a vi or emacs tags file, see **Tagging and Checking Scripts** below.
Here are some common ways to invoke the interpreter:

**pure** Runs the interpreter interactively, without any script. Only the prelude gets loaded.

**pure -g** Runs the interpreter interactively, with debugging support.

**pure -b script ...** Runs the given scripts in batch mode.

**pure -i script ...** Runs the given scripts in batch mode as above, but then enters the interactive command loop. (Add -g to also get debugging support, and -q to suppress the sign-on message.)

**pure script [arg ...]** Runs the given script with the given parameters. The script name and command line arguments are available in the global `argv` variable.

**pure -c script [-o prog]** Batch compilation: Runs the given script, compiling it to a native executable `prog` (a.out by default).

**pure --etags script ... [-T TAGS]** Parses the given scripts and produces an emacs tags file. (Use --ctags to create a vi tags file instead. In either case, the actual name of the tags file can be set with the -T option.)

The following commands provide helpful information about the interpreter, after which the interpreter exits immediately:

**pure --help** Print a short help message describing the command line syntax and available options. This can also be abbreviated as `pure -h`.

**pure --version** Print version information.

Depending on your local setup, there may be additional ways to run the Pure interpreter. In particular, if you have Emacs Pure mode installed, then you can just open a script in Emacs and run it with the C-c C-k keyboard command. For Emacs aficionados, this is probably the most convenient way to execute a Pure script interactively in the interpreter. Pure mode actually turns Emacs into a full IDE (integrated development environment) for Pure, which offers a lot of convenient features such as syntax highlighting, automatic indentation, online help and different ways to interact with the Pure interpreter.

### 1.2.1 Options

The interpreter accepts various options which are described in more detail below.

- **-b**
  Batch mode (execute the given scripts and exit).

- **-c**
  Batch compilation (compile the given scripts to a native binary).

- **--check**
  Syntax check only, do not execute code or produce any output files.

- **--ctags**
- **--etags**
  Create a tags file in ctags (vi) or etags (emacs) format.
--disable optname
    Disable source option (conditional compilation).

--eager-jit
    Enable eager JIT compilation. This requires LLVM 2.7 or later, otherwise this flag will be ignored.

--enable optname
    Enable source option (conditional compilation).

--escape char
    Interactive commands are prefixed with the specified character. Permitted prefixes are: ! $&,*,:<>@\.

-fPIC 
-fpic
    Create position-independent code (batch compilation). (This option will normally be added automatically on platforms where it is needed, so you’ll rarely have to specify this explicitly.)

-g
    Enable symbolic debugging.

-h
    --help
        Print help message and exit.

-i
    Interactive mode (read commands from stdin after sourcing the given scripts, if any).

-I directory
    Add a directory to be searched for included source scripts.

-L directory
    Add a directory to be searched for dynamic libraries.

-l libname
    Library to be linked in batch compilation.

-mopt=val
    Add llc machine options in batch compilation.

--main name
    Name of main entry point in batch compilation.

--noediting
    Disable command-line editing.

-n
    --noprelude
        Do not load the prelude.

--norc
    Do not run the interactive startup files.
-o filename
   Output filename for batch compilation.

-q
   Quiet startup (suppresses sign-on message in interactive mode).

-T filename
   Tags file to be written by --ctags or --etags.

--texmacs
   Run Pure inside TeXmacs.

-u
   Do not strip unused functions in batch compilation.

-v[level]
   Set verbosity level.

--version
   Print version information and exit.

-w
   Enable compiler warnings.

-x
   Script mode (execute a script with the given command line arguments).

--
   Stop option processing and pass the remaining command line arguments in the argv variable.

Besides these, the interpreter also understands a number of other command line switches for setting various compilation options; please see Compilation Options below for details.

---

Note: Option parsing follows the usual (Unix) conventions, but is somewhat more rigid than the GNU getopt conventions. In particular, it is not possible to combine short options, and there are no abbreviations for “long” options. Mixing options and other command line parameters is generally possible, but note that all option processing stops right after -x and -- (or the first non-option parameter in script mode), passing the remaining parameters to the executing script in the Pure argv variable.

As usual, if an option takes a required argument, the argument may be written either as a separate command line parameter immediately following the option (as in -I directory or --enable optname), or directly after the option (-I directory or --enable=optname; note the equals sign in the case of a long option). Options with optional arguments work in the same fashion, but in this case the argument, if present, must be written directly behind the option.

---

1.2.2 Overview of Operation

If any source scripts are specified on the command line, they are loaded and executed, after which the interpreter exits. Otherwise the interpreter enters the interactive read-eval-print
loop, see Running Interactively below. You can also use the \texttt{\textit{-i}} option to enter the interactive loop (continue reading from stdin) even after processing some source scripts.

Options and source files are processed in the order in which they are given on the command line. Processing of options and source files ends when either the \texttt{\textit{--}} or the \texttt{\textit{-x}} option is encountered, or after the first script (non-option) argument in script mode (i.e., if none of the options \texttt{-b, -i, --check, --ctags and --etags}} is present). In either case, any remaining parameters are passed to the executing script by means of the global \texttt{argc} and \texttt{argv} variables, denoting the number of arguments and the list of the actual parameter strings, respectively. In script mode this also includes the script name as \texttt{argv[0]}.

Script mode is useful, in particular, to turn Pure scripts into executable programs by including a “shebang” like the following as the first line in your main script. (This trick only works with Unix shells, though.)

\begin{verbatim}
#!/usr/local/bin/pure
\end{verbatim}

The following variables are always predefined by the interpreter:

\textbf{variable \texttt{argc}}

\textbf{variable \texttt{argv}}

The number of extra command line arguments and the arguments themselves as a list of strings; see above. These are useful if a script is usually run non-interactively and takes its input from the command line.

\textbf{variable \texttt{compiling}}

A flag indicating whether the program is executed in a batch compilation (\texttt{-c} option), see Compiling Scripts below. (This variable is still provided for backward compatibility, but shouldn’t be needed any more and is considered deprecated. The compiler will warn about its use when the \texttt{-w} option is specified.)

\textbf{variable \texttt{version}}

\textbf{variable \texttt{sysinfo}}

The version string of the Pure interpreter and a string identifying the host system. These are useful if parts of your script depend on the particular version of the interpreter and the system it runs on. (An alternative way to deal with version and system dependencies is to use conditional compilation; see Conditional Compilation.)

If available, the prelude script prelude.pure is loaded by the interpreter prior to any other definitions, unless the \texttt{\textit{-n}} or \texttt{\textit{--noprelude}} option is specified. The prelude is searched for in the directory specified with the \texttt{PURELIB} environment variable. If the \texttt{PURELIB} variable is not set, a system-specific default is used. Relative pathnames of other source scripts specified on the command line are interpreted relative to the current working directory. In addition, the executed program may load other scripts and libraries via a \texttt{using} declaration in the source, which are searched for in a number of locations, including the directories named with the \texttt{-I} and \texttt{-L} options; see the Declarations and C Interface sections for details.
1.2.3 Compiling Scripts

The interpreter compiles scripts, as well as definitions that you enter interactively, automatically. This is done in an incremental fashion, as the code is needed, and is therefore known as JIT (just in time) compilation. Thus the interpreter never really “interprets” the source program or some intermediate representation, it just acts as a frontend to the compiler, taking care of compiling source code to native machine code before it gets executed.

Pure’s LLVM backend does “lazy JIT compilation” by default, meaning that each function (global or local) is compiled no sooner than it is run for the first time. With the --eager-jit option, however, it will also compile all other (global or local) functions that may be called by the compiled function. (The PURE_EAGER_JIT environment variable, when set to any value, has the same effect, so that you do not have to specify the --eager-jit option each time you run the interpreter.) Eager JIT compilation may be more efficient in some cases (since bigger chunks of compilation work can be done in one go) and less efficient in others (e.g., eager JITing may compile large chunks of code which aren’t actually called later, except in rare circumstances).

Note that the eager JIT mode is only available with LLVM 2.7 or later; otherwise this option will be ignored.

It is also possible to compile your scripts to native code beforehand, using the -c batch compilation option. This option forces the interpreter to batch mode (unless -i is specified as well, which overrides -c). Any scripts specified on the command line are then compiled as usual (only bypassing immediate execution of toplevel expressions) and the interpreter finally takes a snapshot of the program and outputs it in one of several supported output formats, LLVM assembler (.ll) or bytecode (.bc), native assembler (.s) or object (.o), or a native executable, depending on the output filename specified with -o. If the output filename ends in the .ll extension, an LLVM assembler file is created which can then be processed with the LLVM toolchain. If the output filename is just ‘-’, the assembler file is written to standard output, which is useful if you want to pass the generated code to the LLVM tools in a pipeline. If the output filename ends in the .bc extension, an LLVM bytecode file is created instead.

The .ll and .bc formats are supported natively by the Pure interpreter, no external tools are required to generate these. If the target is an .s, .o or executable file, the Pure interpreter creates a temporary bytecode file on which it invokes the LLVM tools opt and llc to create a native assembler or object file, and then uses the C/C++ compiler to link the resulting program (if requested). You can also specify additional libraries to be linked into the executable with the -l option. If the output filename is omitted, it defaults to a.out (a.exe on Windows).

The C/C++ compiler invoked by the batch compiler is normally gcc by default, but you can change this with the CC and CXX environment variables. The LLVM tools opt and llc are usually located on the PATH or in a system-specific directory determined at installation time. It is also possible to use custom versions of these programs with the batch compiler, by placing them into the Pure library directory, as specified at installation time or by the PURELIB environment variable. (Note that this lets you use the batch compiler on systems which don’t have the LLVM toolchain installed. In fact, you could even deploy a stand-alone version of the interpreter together with the requisite LLVM tools on systems which don’t
have LLVM installed at all, by linking both the Pure runtime and the opt and llc programs statically against LLVM.)

The -c option provides a convenient way to quickly turn a Pure script into a standalone executable which can be invoked directly from the shell. One advantage of compiling your script is that this eliminates the JIT compilation time and thus considerably reduces the startup time of the program. Another reason to prefer a standalone executable is that it lets you deploy the program on systems without a full Pure installation (usually only the runtime library is required on the target system). On the other hand, compiled scripts also have some limitations, mostly concerning the use of the built-in eval function. Please see the Batch Compilation section for details.

The -v64 (or -v0100) verbosity option can be used to have the interpreter print the commands it executes during compilation, see Verbosity and Debugging Options below. When creating an object file, this also prints the suggested linker command (including all the dynamic modules loaded by the script, which also have to be linked in to create a working executable), to which you only have to add the options describing the desired output file.

### 1.2.4 Tagging and Checking Scripts

Pure programs often have declarations and definitions of global symbols scattered out over many different source files. The --ctags and --etags options let you create a tags file which allows you to quickly locate these items in text editors such as vi and emacs which support this feature.

If --ctags or --etags is specified, the interpreter enters a special variation of batch mode in which it only parses source files without executing them and collects information about the locations of global symbol declarations and definitions. The collected information is then written to a tags file in the ctags or etags format used by vi and emacs, respectively. The desired name of the tags file can be specified with the -T option; it defaults to tags for --ctags and TAGS for --etags (which matches the default tags file names used by vi and emacs, respectively).

The tags file contains information about the global constant, variable, macro, function and operator symbols of all scripts specified on the command line, as well as the prelude and other scripts included via a using clause. Tagged scripts which are located in the same directory as the tags file (or, recursively, in one of its subdirectories) are specified using relative pathnames, while scripts outside this hierarchy (such as included scripts from the standard library) are denoted with absolute pathnames. This scheme makes it possible to move an entire directory together with its tags file and have the tags information still work in the new location.

In a similar fashion, the --check option can be used to check scripts for syntax errors; no output files will be produced in this case. This is often used in combination with -w to get warnings about implicit symbol declarations and the like. On-the-fly syntax checkers such as flycheck can employ this facility to check a program while it is being edited (the distribution actually includes a Pure module for flycheck, see Installing Pure (and LLVM) for details).

**Note:** If --check is used along with -w then, in contrast to the tagging options, the syntax
checker will execute global constant and variable definitions. This is necessary in order to
give proper diagnostics about undeclared symbols.

1.2.5 Running Interactively

If the interpreter runs in interactive mode, it repeatedly prompts you for input (which may
be any legal Pure code or some special interpreter commands provided for interactive us-
age), and prints computed results. This is also known as the read-eval-print loop and is
described in much more detail in the Interactive Usage section. To exit the interpreter, just
type the quit command or the end-of-file character (Ctrl-d on Unix) at the beginning of the
command line.

The interpreter may also source a few additional interactive startup files immediately be-
fore entering the interactive loop, unless the --norc option is specified. First .purerc in the
user’s home directory is read, then .purerc in the current working directory. These are ordi-
nary Pure scripts which can be used to provide additional definitions for interactive usage.
Finally, a .pure file in the current directory (usually containing a dump from a previous in-
teractive session) is loaded if it is present.

When the interpreter is in interactive mode and reads from a tty, unless the --noediting
option is specified, commands are usually read using readline or some compatible replace-
ment, providing completion for all commands listed under Interactive Usage, as well as for
symbols defined in the running program. When exiting the interpreter, the command history
is stored in ~/.pure_history, from where it is restored the next time you run the interpreter.

The interpreter also provides a simple source level debugger when run in interactive mode,
see Debugging for details. To enable the debugger, you need to specify the -g option when
invoking the interpreter. This option causes your script to run much slower, so you should
only use this option if you want to run the debugger.

1.2.6 Verbosity and Debugging Options

The -v option is useful for debugging the interpreter, or if you are interested in the code your
program gets compiled to. The level argument is optional; it defaults to 1. Seven different
levels are implemented at this time. Only the first two levels will be useful for the average
Pure programmer; the remaining levels are mostly intended for maintenance purposes.

1 (0x1, 001) denotes echoing of parsed definitions and expressions.

2 (0x2, 002) adds special annotations concerning local bindings (de Bruijn indices, subterm
paths; this can be helpful to debug tricky variable binding issues).

4 (0x4, 004) adds descriptions of the matching automata for the left-hand sides of equations
(you probably want to see this only when working on the guts of the interpreter).

8 (0x8, 010) dumps the “real” output code (LLVM assembler, which is as close to the native
machine code for your program as it gets; you definitely don’t want to see this unless
you have to inspect the generated code for bugs or performance issues).
16 (0x10, 020) adds debugging messages from the bison(1) parser; useful for debugging the parser.

32 (0x20, 040) adds debugging messages from the flex(1) lexer; useful for debugging the lexer.

64 (0x40, 0100) turns on verbose batch compilation; this is useful if you want to see exactly which commands get executed during batch compilation (-c).

These values can be or’ed together, and, for convenience, can be specified in either decimal, hexadecimal or octal. Thus 0xff or 0777 always gives you full debugging output (which isn’t likely to be used by anyone but the Pure developers). Some useful flag combinations for experts are (in octal) 007 (echo definitions along with de Bruijn indices and matching automata), 011 (definitions and assembler code), 021 (parser debugging output along with parsed definitions) and 0100 (verbose batch compilation).

Note that the -v option is only applied after the prelude has been loaded. If you want to debug the prelude, use the -n option and specify the prelude.pure file explicitly on the command line. Verbose output is also suppressed for modules imported through a using clause. As a remedy, you can use the interactive show command (see the Interactive Usage section) to list definitions along with additional debugging information.

1.2.7 Compilation Options

Besides the options listed above, the interpreter also understands some additional command line switches and corresponding environment variables to control various compilation options.

Code Generation Options

These options take the form --opt and --noopt, respectively, where opt denotes the option name (see below for a list of supported options). By default, these options are all enabled; --noopt disables the option, --opt reenables it. In addition, for each option opt there is also a corresponding environment variable PURE_NOOPT (with the option name in uppercase) which, when set, disables the option by default. (Setting this variable to any value will do, the interpreter only checks whether the variable exists in the environment.)

For instance, the checks option controls stack and signal checks. Thus --nochecks on the command line disables the option, and setting the PURE_NOCHECKS environment variable makes this the default, in which case you can use --checks on the command line to reenable the option.

Each code generation option can also be used as a pragma (compiler directive) in source code so that you can control it on a per-rule basis. The pragma must be on a line by itself, starting in column 1, and takes the following form (using --nochecks as an example):

```!
--nochecks // line-oriented comment may go here
```

Currently, the following code generation options are recognized:

--checks
--nochecks
Enable or disable various extra stack and signal checks. By default, the interpreter checks for stack overflows and pending signals on entry to every function, see Stack Size and Tail Recursion and Handling of Asynchronous Signals for details. This is needed to catch these conditions in a reliable way, so we recommend to leave this enabled. However, these checks also make programs run a little slower (typically some 5%, YMMV). If performance is critical then you can disable the checks with the **--nochecks** option. (Even then, a minimal amount of checking will be done, usually on entry to every global function.)

--const
--noconst
Enable or disable the precomputing of constant values in batch compilation (cf. Compiling Scripts). If enabled (which is the default), the values of constants in **const** definitions are precomputed at compile time (if possible) and then stored in the generated executable. This usually yields faster startup times but bigger executables. You can disable this option with **--noconst** to get smaller executables at the expense of slower startup times. Please see the Batch Compilation section for an example.

--fold
--nofold
Enable or disable constant folding in the compiler frontend. This means that constant expressions involving int and double values and the usual arithmetic and logical operations on these are precomputed at compile time. (This is mostly for cosmetic purposes; the LLVM backend will perform this optimization anyway when generating machine code.) For instance:

```plaintext
> foo x = 2*3*x;
> show foo
foo x = 6*x;
```

Disabling constant folding in the frontend causes constant expressions to be shown as you entered them:

```plaintext
> #! --nofold
> bar x = 2*3*x;
> show bar
bar x = 2*3*x;
```

The same option also determines the handling of type aliases at compile time, see Type Rules.

--symbolic
--nosymbolic
Enable or disable **symbolic mode**. Pure’s default behaviour is to evaluate function applications in a symbolic fashion using the equations (rewriting rules) supplied by the programmer, cf. Definitions and Expression Evaluation. This means that it is **not** normally an error if there is no equation which applies to the given function application to be evaluated; rather, the unevaluated function becomes a “constructor symbol” which is applied to the provided arguments to form a literal (“normal form”) term which
stands for itself. E.g., here’s what you get if you try to add an (undefined) symbol and a number:

```plaintext
> a+1;
a+1
```

The `--nosymbolic` option changes this behaviour so that if a global function has *any* defining equations, then an attempt to invoke the function on a combination of arguments for which there is no applicable equation, raises an exception. So if the interpreter is invoked with `--nosymbolic` then you’ll see this instead:

```plaintext
> a+1;
<stdin>, line 1: unhandled exception ‘failed_match’ while evaluating ‘a+1’
```

This behaviour is more in line with traditional languages where it is an error if a “defined function” cannot be evaluated in case of argument mismatch. It makes it easier to spot argument mismatch errors which might well go unnoticed if a program is executed in Pure’s default symbolic mode. However, it also makes it impossible to perform symbolic expression evaluations which is one of the key features of term rewriting as a programming language.

Much of Pure’s library and many programming examples assume Pure’s default mode of symbolic evaluation, so that it is generally not advisable to run the interpreter with a global `--nosymbolic` option, except maybe for debugging purposes. More commonly `--nosymbolic` is used as a pragma in source code where it only applies to a specific collection of function definitions. In addition, there’s a `--defined` pragma which enables you to mark individual functions as “defined functions”, see below.

`--tc`

`--notc`

Enable or disable tail call optimization (TCO). TCO is needed to make tail-recursive functions execute in constant stack space, so we recommend to leave this enabled. However, at the time of this writing LLVM’s TCO support is still bug-ridden on some platforms, so the `--notc` option allows you to disable it. (Note that TCO can also be disabled when compiling the Pure interpreter, in which case these options have no effect; see the installation instructions for details.)

**Note:** All of the options above also have a corresponding “option symbol” so that they can be queried and set using the facilities described under Conditional Compilation below. (The symbol is just the name of the option, e.g., checks for the `--checks`, `--nochecks` option and pragma.)

Besides these, there are the following special pragmas affecting the evaluation of some global function or macro, which is specified in the pragma. These pragmas can only be used in source code, they cannot be controlled using command line options or environment variables. Note that the given symbol `fun` may in fact be an arbitrary symbol (not just an identifier), so that these pragmas can also be applied to special operator symbols (cf. Lexical Matters). Also note that each of these pragmas also implicitly declares the symbol, so if a
symbol needs any special attributes then it must be declared before any pragmas involving it (cf. Symbol Declarations).

**--eager** fun
Instruct the interpreter to JIT-compile the given function eagerly. This means that native code will be created for the function, as well as all other (global or local) functions that may be called by the compiled function, as soon as the function gets recompiled. This avoids the hiccups you get when a function is compiled on the fly if it is run for the first time, which is particularly useful for functions which are to be run in realtime (typically in multimedia applications). Please note that, in difference to the **--eager-jit** option, this feature is available for all LLVM versions (it doesn't require LLVM 2.7 or later).

**--required** fun
Inform the batch compiler (cf. Compiling Scripts) that the given function symbol fun should never be stripped from the program. This is useful, e.g., if a function is never called explicitly but only through eval. Adding a **--required** pragma for the function then makes sure that the function is always linked into the program. Please see the Batch Compilation section for an example.

**--defined** fun
**--nodefined** fun
These pragmas change the behaviour of global functions defined in a Pure program. The **--defined** pragma marks the given function or operator symbol as a “defined function” so that an exception is raised if the function is applied to a combination of arguments for which there is no applicable equation. This works similarly to the **--nosymbolic** pragma (see above), but allows you to mark individual functions as “defined”. For instance:

```plaintext
> #! --defined +
> a+1;
<stdin>, line 2: unhandled exception 'failed_match' while evaluating 'a+1'
```

The **--defined** status of a function can be changed at any time (causing the function to be recompiled on the fly if necessary), and the **--nodefined** pragma restores the default behaviour of returning a normal form upon failure:

```plaintext
> #! --nodefined +
> a+1;
a+1
```

More information and examples for common uses of the **--defined** and **--nosymbolic** pragmas can be found under Defined Functions in the Caveats and Notes section.

**--quoteargs** fun
This pragma tells the macro evaluator (cf. Macros) that the given macro should receive its arguments unevaluated, i.e., in quoted form. This is described in more detail in the Built-in Macros and Special Expressions section.
Conditional Compilation

As of version 0.49, Pure also provides a rudimentary facility for denoting optional and alternative code paths. This is supposed to cover the most common cases where conditional compilation is needed. (For more elaborate needs you can always use real Pure code which enables you to configure your program at runtime using, e.g., the `eval` function.)

Pure's conditional compilation pragmas are based on the notion of user-defined symbols (which can be really any text that does not contain whitespace or any of the shell wildcard characters `*?[]`) called compilation **options**. By default, all options are *undefined* and *enabled*. An option becomes *defined* as soon as it is set explicitly, either with an environment variable or one of the `--enable` and `--disable` pragmas, see below.

You can define the value of an option by setting a corresponding environment variable `PURE_OPTION_OPT`, where `OPT` is the option symbol in uppercase. The value of the environment variable should either be 0 (disabled) or 1 (enabled).

Options can be enabled and disabled in Pure scripts with the following pragmas, which are also available as command line options when invoking the Pure interpreter:

`--enable option`

`--disable option`

Enable or disable the given option, respectively. Note that an option specified in the environment is overridden by a value specified with these options on the command line, which in turn is overridden by a corresponding pragma in source code.

The actual conditional compilation pragmas work in pretty much the same fashion as the C preprocessor directives `#if`, `#ifdef` etc. (except that, as already mentioned, an option is always enabled if it is undefined).

`--ifdef option`

`--ifndef option`

Begins a code section which should be included in the program if the given option is defined or undefined, respectively.

`--if option`

`--ifnot option`

Begins a code section which should be included in the program if the given option is enabled or disabled, respectively.

`--else`

Begins an alternative code section which is included in the program if the corresponding `--ifdef`, `--ifndef`, `--if` or `--ifnot` section was excluded, and vice versa.

`--endif`

Ends a conditional code section.

Conditional code sections may be nested to an arbitrary depth. Each `--ifdef`, `--ifndef`, `--if` or `--ifnot` pragma must be followed by a matching `--endif`. The `--else` section is optional; if present, it applies to the most recent `--ifdef`, `--ifndef`, `--if` or `--ifnot` section not terminated by a matching `--endif`. Unmatched conditional pragmas warrant an error message by the compiler.
Conditional code is handled at the level of the lexical analyzer. Excluded code sections are treated like comments, i.e., the parser never gets to see them.

The `--ifdef` and `--ifndef` pragmas are typically used to change the default of an option without clobbering defaults set by the user through an environment variable or a command line option. For instance:

```plaintext
#!/ --ifndef opt
#!/ --disable opt
#!/ --endif
```

Here's a (rather contrived) example which shows all these pragmas in action. You may want to type this in the interpreter to verify that the code sections are indeed included and excluded from the Pure program as indicated:

```plaintext
// disable the 'bar' option
#!/ --disable bar

#!/ --ifdef foo
1/2; // excluded
#!/ --endif

#!/ --ifndef bar
1/3; // excluded
#!/ --endif

#!/ --if foo
foo x = x+1; // included
#!/ --endif

#!/ --if bar
bar x = x-1; // excluded
#!/ --else
bar x = x/2; // included
#!/ --endif // bar
#!/ --endif // foo

// reenable the 'bar' option
#!/ --enable bar

#!/ --if bar
bar 99; // included
#!/ --endif // bar

#!/ --ifnot foo
baz x = 2*x; // excluded
#!/ --endif // not foo
```

A few options are always predefined as “builtins” by the interpreter. This includes all of the options described under Code Generation Options and Warning Options, so that these can also be queried with `--if`, `--ifnot` and set with `--enable, --disable`. For instance:

```plaintext
#!/ --ifnot checks
puts "This program uses deep recursion, so we enable stack checks here!";
#!/ --enable checks
#!/ --endif // not checks
```
Moreover, the following options are provided as additional builtins which are useful for handling special compilation requirements as well as system and version dependencies.

- The compiled option is enabled if a program is batch-compiled. This lets you pick alternative code paths depending on whether a script is compiled to a native executable or not. Please see the example at the end of the Batch Compilation section for details.

- The interactive and debugging options are enabled if a program runs in interactive (-i) and/or debugging (-g) mode, respectively. These options are read-only; they cannot be changed with --enable, --disable. Example:

```plaintext
#!/ --if interactive
puts "Usage: run 'main filename';"
#!/ --else
main (argv!1);
#!/ --endif
```

- The version-\textit{x.y} option indicates a check against the version of the host Pure interpreter. \textit{x.y} indicates the required (major/minor) version. You can also use \textit{x.y+} to indicate version \textit{x.y} or later, or \textit{x.y-} for version \textit{x.y} or earlier. By combining these, you can pick code depending on a particular range of Pure versions, or you can reverse the test to check for anything later or earlier than a given version:

```plaintext
#!/ --if version-0.36+
#!/ --if version-0.48-
// code to be executed for Pure versions 0.36..0.48 (inclusive)
#!/ --endif
#!/ --endif

#!/ --ifnot version-0.48-
// code to be executed for Pure versions > 0.48
#!/ --endif
```

- Last but not least, the interpreter always defines the target triplet of the host system as an option symbol. This is the same as what \texttt{sysinfo} returns, so you can check for a specific system like this:

```plaintext
#!/ --if x86_64-unknown-linux-gnu
// 64 bit Linux-specific code goes here
#!/ --endif
```

It goes without saying that this method isn’t very practical if you want to check for a wide range of systems. As a remedy, the \texttt{--if} and \texttt{--ifnot} pragmas treat shell glob patterns in tests for option symbols in a special way, by matching the pattern against the host triplet to see whether the condition holds. This allows you to write a generic test, e.g., for Windows systems like this:
Warning Options

The `-w` option enables some additional warnings which are useful to check your scripts for possible errors. In particular, it will report implicit declarations of function and type symbols, which might indicate undefined or mistyped symbols that need to be fixed, see Symbol Lookup and Creation for details.

This option can also be controlled on a per-rule basis by adding the following pragmas to your script:

```pure
--warn
--nowarn
```

Enable or disable compiler warnings. The `-w` flag sets the default for these pragmas.

```
--rewarn
```

Reset compiler warnings to the default, as set with the `-w` flag (or not).

The latter pragma is useful to enable or disable warnings in a section of code and reset it to the default afterwards:

```pure
#! --warn
// Code with warnings goes here.
#! --rewarn
```

(The same could also be achieved with conditional compilation, but only much more clumsily. However, note that `--rewarn` only provides a single level of “backup”, so nesting such sections is not supported.)

1.2.8 Startup Files

The interpreter may source various files during its startup. These are:

```
~/.pure_history
```

Interactive command history.

```
~/.purerc, .purerc, .pure
```

Interactive startup files. The latter is usually a dump from a previous interactive session.

```
prelude.pure
```

Standard prelude. If available, this script is loaded before any other definitions, unless `-n` was specified.

1.2.9 Environment

Various aspects of the interpreter can be configured through the following shell environment variables:
CC
C and C++ compiler used by the Pure batch compiler (pure -c) to compile and link native executables. Defaults to gcc and g++, respectively.

BROWSER
If the PURE_HELP variable is not set (see below), this specifies a colon-separated list of browsers to try for reading the online documentation. See http://catb.org/~esr/BROWSER/.

PURELIB
Directory to search for library scripts, including the prelude. If PURELIB is not set, it defaults to some location specified at installation time.

PURE_EAGER_JIT
Enable eager JIT compilation (same as --eager-jit), see Compiling Scripts for details.

PURE_ESCAPE
If set, interactive commands are prefixed with the first character in the value of this variable (same as --escape), see Interactive Usage for details.

PURE_HELP
Command used to browse the Pure manual. This must be a browser capable of displaying html files. Default is w3m.

PURE_INCLUDE
Additional directories (in colon-separated format) to be searched for included scripts.

PURE_LIBRARY
Additional directories (in colon-separated format) to be searched for dynamic libraries.

PURE_MORE
Shell command to be used for paging through output of the show command, when the interpreter runs in interactive mode. PURE_LESS does the same for evaluation results printed by the interpreter.

PURE_PS
Command prompt used in the interactive command loop (“> ” by default).

PURE_STACK
Maximum stack size in kilobytes (0 = unlimited). A reasonable default is provided (currently this is always 8192K - 128K for interpreter and runtime, which should work on most modern PCs). If you’re still getting segfaults due to stack overflow then you’ll either have to reduce this value or increase the actual stack space available to programs.

Besides these, the interpreter also understands a number of other environment variables for setting various compilation options (see Compilation Options above) and commands to invoke different LLVM compilers on inline code (see Inline Code).
1.3 Pure Overview

Pure is a fairly simple yet powerful language. Programs are basically collections of term rewriting rules, which are used to reduce expressions to normal form in a symbolic fashion. For convenience, Pure also offers some extensions to the basic term rewriting calculus, like global variables and constants, nested scopes of local function and variable definitions, anonymous functions (lambdas), exception handling and a built-in macro facility. These are all described below and in the following sections.

Most basic operations are defined in the standard prelude. This includes the usual arithmetic and logical operations, as well as the basic string, list and matrix functions. The prelude is always loaded by the interpreter, so that you can start using the interpreter as a sophisticated kind of desktop calculator right away. Other useful operations are provided through separate library modules. Some of these, like the system interface and the container data structures, are distributed with the interpreter, others are available as separate add-on packages from the Pure website. A (very) brief overview of some of the modules distributed with the Pure interpreter can be found in the Standard Library section.

In this section we first give a brief overview of the most important elements of the Pure language. After starting out with a discussion of the lexical syntax, we proceed by explaining definitions and expressions, which are the major ingredients of Pure programs. After studying this section you should be able to write simple Pure programs. Subsequent sections then describe the concepts and notions introduced here in much greater detail and also cover the more advanced language elements which we only gloss over here.

1.3.1 Lexical Matters

Pure is a free-format language, i.e., whitespace is insignificant (unless it is used to delimit other symbols). Thus, in contrast to “layout-based” languages like Haskell, you must use the proper delimiters (;) and keywords (end) to terminate definitions and block structures. In particular, definitions and expressions at the toplevel have to be terminated with a semicolon, even if you’re typing them interactively in the interpreter.

Comments use the same syntax as in C++: // for line-oriented, and /* . . . */ for multiline comments. The latter must not be nested. Lines beginning with #! are treated as comments, too; as already discussed above, on Unix-like systems this allows you to add a “shebang” to your main script in order to turn it into an executable program.

A few ASCII symbols are reserved for special uses, namely the semicolon, the “at” symbol @, the equals sign =, the backslash \, the Unix pipe symbol |, parentheses (), brackets [] and curly braces {}. (Among these, only the semicolon is a “hard delimiter” which is always a lexeme by itself; the other symbols can be used inside operator symbols.) Moreover, there are some keywords which cannot be used as identifiers:

```
case const def else end extern if
infix infixl infixr interface let namespace nonfix
of otherwise outfix postfix prefix private public
then type using when with
```

Pure fully supports the Unicode character set or, more precisely, UTF-8. This is an ASCII ex-
tension capable of representing all Unicode characters, which provides you with thousands of characters from most of the languages of the world, as well as an abundance of special symbols for almost any purpose. If your text editor supports the UTF-8 encoding (most editors do nowadays), you can use all Unicode characters in your Pure programs, not only inside strings, but also for denoting identifiers and special operator symbols.

The customary notations for identifiers, numbers and strings are all provided. In addition, Pure also allows you to define your own operator symbols. Identifiers and other symbols are described by the following grammar rules in EBNF format:

```
symbol ::= identifier | special
identifier ::= letter (letter | digit)*
special ::= punct+
letter ::= "A" | ... | "Z" | "a" | ... | "z" | "_" | ...
digit ::= "0" | ... | "9"
punct ::= "!" | "#" | "$" | "%" | "&" | ...
```

Pure uses the following rules to distinguish “punctuation” (which may only occur in declared operator symbols) and “letters” (identifier constituents). In addition to the punctuation symbols in the 7 bit ASCII range, the following code points in the Unicode repertoire are considered as punctuation: U+00A1 through U+00BF, U+00D7, U+00F7, and U+20D0 through U+2BFF. This comprises the special symbols in the Latin-1 repertoire, as well as the Combining Diacritical Marks for Symbols, Letterlike Symbols, Number Forms, Arrows, Mathematical Symbols, Miscellaneous Technical Symbols, Control Pictures, OCR, Enclosed Alphanumerics, Box Drawing, Blocks, Geometric Shapes, Miscellaneous Symbols, Dingbats, Miscellaneous Mathematical Symbols A, Supplemental Arrows A, Supplemental Arrows B, Miscellaneous Mathematical Symbols B, Supplemental Mathematical Operators, and Miscellaneous Symbols and Arrows. This should cover almost everything you’d ever want to use in an operator symbol. All other extended Unicode characters are effectively treated as “letters” which can be used as identifier constituents. (Charts of all Unicode symbols can be found at the Code Charts page of the Unicode Consortium.)

The following are examples of valid identifiers: foo, foo_bar, FooBar, BAR, bar99. Case is significant in identifiers, so Bar and bar are distinct identifiers, but otherwise the case of letters carries no meaning. Special symbols consist entirely of punctuation, such as ::=. These may be used as operator symbols, but have to be declared before they can be used (see Symbol Declarations).

Pure also has a notation for qualified symbols which carry a namespace prefix. These take the following format (note that no whitespace is permitted between the namespace prefix and the symbol):

```
qualified_symbol ::= [qualifier] symbol
qualified_identifier ::= [qualifier] identifier
qualified ::=: [identifier] "::" (identifier "::")*
```

Example: foo::bar.

Number literals come in three flavours: integers, bigints (denoted with an L suffix) and
floating point numbers (indicated by the presence of the decimal point and/or a base 10 scaling factor). Integers and bigints may be written in different bases (decimal, binary, octal and hexadecimal), while floating point numbers are always denoted in decimal.

```
number ::= integer | integer "L" | float
integer ::= digit+
    | "0" ("X"|"x") hex_digit+
    | "0" ("B"|"b") bin_digit+
    | "0" oct_digit+
oct_digit ::= "0"|...|"7"
hex_digit ::= "0"|...|"9"|"A"|...|"F"|"a"|...|"f"
bin_digit ::= "0"|"1"
float ::= digit+ ["." digit+] exponent
    | digit* "." digit+ [exponent]
exponent ::= ("E"|"e") ["+"|"-"|"."] digit+
```

Examples: 4711, 4711L, 1.2e-3. Numbers in different bases: 1000 (decimal), 0x3e8 (hexadecimal), 01750 (octal), 0b1111101000 (binary).

String literals are arbitrary sequences of characters enclosed in double quotes, such as "Hello, world!".

```
string ::= "" char* ""
```

Special escape sequences may be used to denote double quotes and backslashes (\", \"), control characters (\b, \f, \n, \r, \t, these have the same meaning as in C), and arbitrary Unicode characters given by their number or XML entity name (e.g., \169, \0xa9 and \© all denote the Unicode copyright character, code point U+00A9). As indicated, numeric escapes can be specified in any of the supported bases for integer literals. For disambiguating purposes, these can also be enclosed in parentheses. E.g., \((123)4" is a string consisting of the character \123 followed by the digit 4. Strings can also be continued across line ends by escaping the line end with a backslash. The escaped line end is ignored (use \n if you need to embed a newline in a string). For instance,

"Hello, \n world.\n"

denotes the same string literal as

"Hello, world.\n"

### 1.3.2 Definitions and Expression Evaluation

The real meat of a Pure program is in its definitions. In Pure these generally take the form of equations which tell the interpreter how expressions are to be evaluated. For instance, the following two equations together define a function `fact` which computes, for each given integer `n`, the factorial of `n`:
fact 0 = 1;
fact n::int = n*fact (n-1) if n>0;

The first equation covers the case that \( n \) is zero, in which case the result is 1. The second equation handles the case of a positive integer. Note the \( n::\text{int} \) construct on the left-hand side, which means that the equation is restricted to (machine) integers \( n \). This construct is also called a “type tag” in Pure parlance. In addition, the \( n>0 \) in the condition part of the second equation ensures that \( n \) is positive. If these conditions are met, the equation becomes applicable and we recursively compute \( \text{fact} \ (n-1) \) and multiply by \( n \) to obtain the result. The \text{fact} \ function thus computes the product of all positive integers up to \( n \), which is indeed just how the factorial is defined in mathematics.

To give this definition a try, you can just enter it at the command prompt of the interpreter as follows:

\[
> \text{fact} \ 0 = 1;
> \text{fact} \ n::\text{int} = n*\text{fact} \ (n-1) \ \text{if} \ n>0;
> \text{fact} \ 10;
3628800
\]

On the surface, Pure is quite similar to other modern functional languages like Haskell and ML. But under the hood it is a much more dynamic language, more akin to Lisp. In particular, Pure is dynamically typed, so functions can process arguments of as many different types as you like. In fact, you can add to the definition of an existing function at any time. For instance, we can extend our example above to make the \text{fact} \ function work with floating point numbers, too:

\[
> \text{fact} \ 0.0 = 1.0;
> \text{fact} \ n::\text{double} = n*\text{fact} \ (n-1) \ \text{if} \ n>0;
> \text{fact} \ 10.0;
3628800.0
\]

Here we employed the constant \( 0.0 \) and the \text{double} \ type tag to define the factorial for the case of floating point numbers. Both \text{int} \ and \text{double} \ are built-in types of the Pure language. Our earlier definition for the \text{int} \ case still works as well:

\[
> \text{fact} \ 10;
3628800
\]

In FP parlance, we say that a function like \text{fact} \ is\textbf{ polymorphic}, because it applies to different argument types. More precisely, the kind of polymorphism at work here is \textbf{ad-hoc polymorphism}, because we have two distinct definitions of the same function which behave differently for different argument types.

Note that in this specific case, the two definitions are in fact very similar, to the point that the right-hand sides of the definitions are almost the same. Observing these similarities, we may also define \text{fact} \ in a completely generic way:

\[
> \text{clear fact}
> \text{fact} \ n = 1 \ \text{if} \ n==0;
> \text{fact} \ n = n*\text{fact} \ (n-1) \ \text{if} \ n>0;
\]
(Note that before we can enter the new definition, we first need to scratch our previous definition of fact, that's what the clear fact command does. This is necessary because, as we already saw, the interpreter would otherwise just keep adding equations to the definition of fact that we already have.)

Our new definition doesn’t have any type tags on the left-hand side and will thus work with any type of numbers:

```plaintext
> fact 10; // int
3628800
> fact 30.0; // floating point
2.65252859812191e+32
> fact 50L; // bigint
30414093201713378043612608166064768844377641568960512000000000000L
```

Let’s now take a look at how the equations are actually applied in the evaluation process. Conceptually, Pure employs term rewriting as its underlying model of computation, so the equations are applied as rewriting rules, reading them from left to right. An equation is applicable if its left-hand side matches the target term to be evaluated, in which case we can bind the variables in the left-hand side to the corresponding subterms in the target term. Equations are tried in the order in which they are written; as soon as the left-hand side of an equation matches (and the condition part of the equation, if any, is satisfied), it can be applied to reduce the target term to the corresponding right-hand side.

For instance, let’s take a look at the target term `fact 3`. This matches both equations of our generic definition of `fact` from above, with `n` bound to `3`. But the condition `3==0` of the first equation fails, so we come to consider the second equation, whose condition `3>0` holds. Thus we can perform the reduction `fact 3 ==> 3*fact (3-1)` and then evaluate the new target term `3*fact (3-1)` recursively.

At this point, we have to decide which of the several subterms we should reduce first. This is also called the reduction strategy and there are different ways to go about it. For instance, we might follow the customary “call-by-value” strategy where the arguments of a function application are evaluated recursively before the function gets applied to it, and this is also what Pure normally does. More precisely, expressions are evaluated using the “leftmost-innermost” reduction strategy where the arguments are considered from left to right.

So this means that on the right-hand side of the second equation, first `n-1` (being the argument of `fact`) is evaluated, then `fact (n-1)` (which is an argument to the `*` operator), and finally `fact (n-1)` is multiplied by `n` to give the value of `fact n`. Thus the evaluation of `fact 3` actually proceeds as follows (abbreviating reductions for the built-in arithmetic operations):

```
fact 3 => 3*fact 2 => 3*2*fact 1 => 3*2*1*fact 0 => 3*2*1*1 => 6.
```

We mention in passing here that Pure also has a few built-in “special forms” which take some or all of their arguments unevaluated, using “call by name” argument passing. This is needed to handle some constructs such as logical operations and conditionals in an efficient manner, and it also provides a way to implement “lazy” data structures. We’ll learn about these later.
One of the convenient aspects of the rewriting model of computation is that it enables you to define a function by pattern matching on structured argument types. For instance, we might compute the sum of the elements of a list as follows:

```plaintext
> sum [] = 0;
> sum (x:xs) = x+sum xs;
```

This discriminates over the different cases for the argument value which might either be the empty list `[]` or a non-empty list of the from `x:xs` where the variables `x` and `xs` refer to the head element and the rest of the list, respectively. (The ‘:’ infix operator is Pure’s way of writing Lisp’s “cons”; this works the same as in other modern FPLs and is discussed in much more detail later.)

Let’s give it a try:

```plaintext
> sum (1..10);
55
```

Note that `1..10` denotes the list of all positive integers up to 10 here, so we get the sum of the numbers 1 thru 10 as the result, which is indeed 55. (The ‘..’ operation is provided in Pure’s prelude, i.e., it is part of the standard library.)

Due to its term rewriting semantics, Pure actually goes beyond most other functional languages in that it can do symbolic evaluations just as well as “normal” computations:

```plaintext
> square x = x*x;
> square 4;
16
> square (a+b);
(a+b)*(a+b)
```

In fact, leaving aside the built-in support for some common data structures such as numbers and strings, all the Pure interpreter really does is evaluate expressions in a symbolic fashion, rewriting expressions using the equations supplied by the programmer, until no more equations are applicable. The result of this process is called a normal form which represents the “value” of the original expression. Moreover, there’s no distinction between “defined” and “constructor” function symbols in Pure, so any function symbol or operator can be used anywhere on the left-hand side of an equation, and may act as a constructor symbol if it happens to occur in a normal form term. This enables you to work with algebraic rules like associativity and distributivity in a direct fashion:

```plaintext
> (x+y)*z = x*z+y*z; x*(y+z) = x*y+x*z;
> x*(y+z) = (x*y)+z; x+(y+z) = (x+y)+z;
> square (a+b);
(a+b)*(a+b)
```

The above isn’t possible in languages like Haskell and ML which always enforce that only “pure” constructor symbols (without any defining equations) may occur as a subterm on the left-hand side of a definition; this is also known as the constructor discipline. Thus equational definitions like the above are forbidden in these languages. Pure doesn’t enforce the constructor discipline, so it doesn’t keep you from writing such symbolic rules if you need them.
Another way of looking at this is that Pure allows you to have constructor equations. For instance, the following equation makes lists automatically stay sorted:

```plaintext
> x:y:xs = y:x:xs if x>y;
> [13,7,9,7,1]+[1,9,7,5];
[1,1,5,7,7,9,9,13]
```

This isn’t possible in Haskell and ML either because it violates the constructor discipline; since ‘:’ is a constructor it can’t simultaneously be a defined function in these languages. Pure gives you much more freedom there.

This symbolic mode of evaluation is rather unusual outside of the realm of symbolic algebra systems, but it provides the programmer with a very flexible model of computation and is one of Pure’s most distinguishing features. In some cases, however, the unevaluated normal forms may also become a nuisance since they may obscure possible programming errors. Therefore Pure provides special `--nosymbolic` and `--defined` pragmas (cf. Code Generation Options) which force functions to be treated as defined functions, so that they become more like functions in traditional untyped languages such as Lisp and Python which raise an exception under such conditions. This is described in more detail under Defined Functions in the Caveats and Notes section.

**Variables in Equations**

Taking another look at the examples above, you might wonder how the Pure interpreter figures out what the parameters (a.k.a. “variables”) in an equation are. This is quite obvious in rules involving just variables and special operator symbols, such as \((x+y)\times z = x\times z + y\times z\). However, what about an equation like `foo (foo bar) = bar`? Since most of the time we don’t declare any symbols in Pure, how does the interpreter know that `foo` is a literal function symbol here, while `bar` is a variable?

The answer is that the interpreter considers the different positions in the left-hand side expression of an equation. Basically, a Pure expression is just a tree formed by applying expressions to other expressions, with the atomic subexpressions like numbers and symbols at the leaves of the tree. (This is true even for infix expressions like `x+y`, since in Pure these are always equivalent to a function application of the form `(+) x y` which has the atomic subterms `(+)`, `x` and `y` at its leaves.)

Now the interpreter divides the leaves of the expression tree into “head” (or “function”) and “parameter” (or “variable”) positions based on which leaves are leftmost in a function application or not. Thus, in an expression like `f x y z`, `f` is in the head or function position, while `x`, `y` and `z` are in parameter or variable positions. (Note that in an infix expression like `x+y`, `+` is the head symbol, not `x`, as the expression is really parsed as `(+) x y`, see above.)

Identifiers in head positions are taken as literal function symbols by the interpreter, while identifiers in variable positions denote, well, variables. We also refer to this convention as the head = function rule. It is quite intuitive and lets us get away without declaring the variables in equations. (There are some corner cases not covered here, however. In particular, Pure allows you to declare special “nonfix” symbols, if you need a symbol to be recognized as a literal even if it occurs in a variable position. This is done by means of a nonfix declaration, see Symbol Declarations for details.)
1.3.3 Expression Syntax

Like in other functional languages, expressions are the central ingredient of all Pure programs. All computation performed by a Pure program consists in the evaluation of expressions, and expressions also form the building blocks of the equational rules which are used to define the constants, variables, functions and macros of a Pure program.

Typical examples of the different expression types are summarized in the following table. Note that lambdas bind most weakly, followed by the special case, when and with constructs, followed by conditional expressions (if-then-else), followed by the simple expressions. Operators are a part of the simple expression syntax, and are parsed according to their declared precedences and associativities (cf. Symbol Declarations). Function application binds stronger than all operators. Parentheses can be used to group expressions and override default precedences as usual.

The formal syntax of expressions is as follows. (Note that the rule and simple_rule elements are part of the definition syntax, which is explained in the Rule Syntax section.)
expr ::= "\" prim_expr+ "->" expr
    | "case" expr "of" rules "end"
    | expr "when" simple_rules "end"
    | expr "with" rules "end"
    | "if" expr "then" expr "else" expr
    | simple_expr

simple_expr ::= simple_expr op simple_expr
    | op simple_expr
    | simple_expr op

application ::= application prim_expr
    | prim_expr

prim_expr ::= qualified_symbol
    | number
    | string
    | "{" op "}"
    | "{" left_op right_op "}"
    | "{" simple_expr op "}"
    | "{" op simple_expr "}"
    | "{" expr "}"
    | left_op expr right_op
    | "{" exprs "}"
    | "{" exprs ("," exprs)* [";"] "}" 
    | "{" expr [" simple_rules "]}
    | "{" expr [" simple_rules "]"

exprs ::= expr ("," expr)*

op ::= qualified_symbol

left_op ::= qualified_symbol

right_op ::= qualified_symbol

rules ::= rule ("," rule)* [";"]

simple_rules ::= simple_rule ("," simple_rule)* [";"]

Primary Expressions

The Pure language provides built-in support for machine integers (32 bit), bigints (implemented using GMP), floating point values (double precision IEEE 754) and character strings (UTF-8 encoded). These can all be denoted using the corresponding literals described in Lexical Matters. Truth values are encoded as machine integers; as you might expect, zero denotes false and any non-zero value true, and the prelude also provides symbolic constants false and true to denote these. Pure also supports generic C pointers, but these don’t have a syntactic representation in Pure, except that the predefined constant NULL may be used to denote a generic null pointer; other pointer values need to be created with external C functions.

Together, these atomic types of expressions make up most of Pure’s primary expression syntax. Pure also provides built-in support for some types of “compound primaries” (lists,
tuples and matrices). We also list these here since they are typically denoted in some kind of bracketed form, even though some related non-primary expression types such as x:y or x,y really belong to the simple expressions.

Numbers: 4711, 4711L, 1.2e-3
The usual C notations for integers (decimal: 1000, hexadecimal: 0x3e8, octal: 01750) and floating point values are all provided. Integers can also be denoted in base 2 by using the 0b or 0B prefix: 0b1111101000. Integer constants that are too large to fit into machine integers are promoted to bigints automatically. Moreover, integer literals immediately followed by the uppercase letter L are always interpreted as bigint constants, even if they fit into machine integers. This notation is also used when printing bigint constants, to distinguish them from machine integers.

Strings: "Hello, world!\n"
String constants are double-quoted and terminated with a null character, like in C. In contrast to C, strings are always encoded in UTF-8, and character escapes in Pure strings have a more flexible syntax (borrowed from the author’s Q language) which provides notations to specify any Unicode character. Please refer to Lexical Matters for details.

Function and variable symbols: foo, foo_bar, BAR, foo::bar
These consist of the usual sequence of letters (including the underscore) and digits, starting with a letter. Case is significant, thus foo, Foo and F00 are distinct identifiers. The ‘_’ symbol, when occurring on the left-hand side of an equation, is special; it denotes the anonymous variable which matches any value without actually binding a variable. Identifiers can also be prefixed with a namespace identifier, like in foo::bar. (This requires that the given namespace has already been created, as explained under Namespaces in the Declarations section.)

Operator symbols: +, ==, not
For convenience, Pure also provides you with a limited means to extend the syntax of the language with special operator symbols by means of a corresponding fixity declaration, as discussed in section Symbol Declarations. Besides the usual infix, prefix and postfix operators, Pure also provides outfix (bracket) and nonfix (nullary operator) symbols. (Nonfix symbols actually work more or less like ordinary identifiers, but the nonfix attribute tells the compiler that when such a symbol occurs on the left-hand side of an equation, it is always to be interpreted as a literal, cf. The “Head = Function” Rule.)

Operator (and nonfix) symbols may take the form of an identifier or a sequence of punctuation characters, which may optionally be qualified with a namespace prefix. These symbols must always be declared before use. Once declared, they are always special, and can’t be used as ordinary identifiers any more. However, like in Haskell, by enclosing an operator in parentheses, such as (+) or (not), you can turn it into an ordinary function symbol.

Lists: [x,y,z], x:xs
Pure’s basic list syntax is the same as in Haskell, thus [] is the empty list and x:xs denotes a list with head element x and tail list xs. The infix constructor symbol ‘:’ is declared in the prelude. It associates to the right, so that x:y:z is the same as x:(y:z).
The usual syntactic sugar for list values in brackets is also provided, thus \([x,y,z]\) is exactly the same as \(x:y:z:[]\). (This kind of list value is also called a “proper” list. Pure also permits “improper” list values such as \(1:2:3\) with a non-list value in the tail. These aren’t of much use as ordinary list values, but are frequently used in patterns or symbolic expressions such as \(x:y\) where the tail usually is a variable.)

Lists can be nested to an arbitrary depth. Also note that, in contrast to Haskell, lists are not required to be homogeneous, so in general they may contain an arbitrary mix of element types. E.g., \([1,2.0,[x,y]]\) is a three-element list consisting of an integer, a floating point number and a nested list containing two symbols.

Pure also provides a notation for arithmetic sequences such as \(1..5\), which denotes the list \([1,2,3,4,5]\). Note the missing brackets; Pure doesn’t use any special syntax for arithmetic sequences, the ‘..’ symbol is just an ordinary infix operator declared and defined in the prelude. Sequences with arbitrary stepsizes can be written by denoting the first two sequence elements using the ‘:’ operator, as in \(1.0:1.2..3.0\). To prevent unwanted artifacts due to rounding errors, the upper bound in a floating point sequence is always rounded to the nearest grid point. Thus, e.g., \(0.0:0.1..0.29\) actually yields \([0.0,0.1,0.2,0.3]\), as does \(0.0:0.1..0.31\).  

**Tuples: \((x,y,z)\)**

Pure’s tuples are a flat variant of lists which are often used as aggregate function arguments and results when no elaborate hierarchical structure is needed. They are constructed using the infix “pairing” operator ‘,’, for which the empty tuple () acts as a neutral element (i.e., (),\(x\) is just \(x\), as is \(x,()\)). Pairs always associate to the right, meaning that \(x,y,z = x,(y,z) = (x,y),z\), where \(x,(y,z)\) is the normalized representation. These rules imply that tuples can’t be nested and that there are no “true” 1-tuples distinct from their single members; if you need this then you should use lists instead (cf. Splicing Tuples and Matrices).

Note that the parentheses are not really part of the tuple syntax in Pure, they’re just used to group expressions. So \((x,y,z)\) denotes just \(x,y,z\). But since the ‘,’ operator has a low precedence, the parentheses are often needed to include tuples in other contexts. In particular, the parentheses are required to set off tuple elements in lists and matrices. E.g., \([(1,2),3,(4,5)]\) denotes a three element list consisting of two tuples and an integer.

Mathematically, Pure’s notion of tuples corresponds to a monoid with an associative binary operation ‘,’ and neutral element (). This is different from the usual definition of tuples in mathematical logic, which are nestable and correspond to Pure’s notion of lists. So in Pure you can take your pick and use either flat tuples or nestable lists, whatever is most convenient for the problem at hand.

**Matrices: \(\{1.0,2.0,3.0\}, \{1,2;3,4\}, \{\cos t,-\sin t;\sin t,\cos t\}\)**

Pure also offers matrices, a kind of two-dimensional arrays, as a built-in data structure which provides efficient storage and element access. These work more or less like their Octave/MATLAB equivalents, but using curly braces instead of brackets. Component values may either be individual elements (“scalars”) or submatrices which are combined to form a larger matrix, provided that all dimensions match up. Here, a scalar is any expression which doesn’t yield a matrix; these are considered to be 1x1 sub-
matrices for the purpose of matrix construction. (Note that this “splicing” behaviour pertains to matrix construction only; nested matrix patterns are always matched literally.)

The comma arranges submatrices and scalars in columns, while the semicolon arranges them in rows. So, if both \(x\) and \(y\) are \(n \times m\) matrices, then \(\{x, y\}\) becomes an \(n \times 2m\) matrix consisting of all the columns of \(x\) followed by all the columns of \(y\). Likewise, \(\{x; y\}\) becomes a \(2n \times m\) matrix (all the rows of \(x\) above of all rows of \(y\)). For instance, \(\{1;3\}, \{2;4\}\) is another way to write the \(2 \times 2\) matrix \(\{1,2;3,4\}\). Row vectors are denoted as \(1 \times n\) matrices (\(\{1,2,3\}\)), column vectors as \(n \times 1\) matrices (\(\{1;2;3\}\)).

More examples can be found in the Matrices and Vectors section.

Pure supports both numeric and symbolic matrices. The former are homogeneous arrays of double, complex double or (machine) int matrices, while the latter can contain any mixture of Pure expressions. Pure will pick the appropriate type for the data at hand. If a matrix contains values of different types, or Pure values which cannot be stored in a numeric matrix, then a symbolic matrix is created instead (this also includes the case of bigints, which are considered as symbolic values as far as matrix construction is concerned). Numeric matrices use an internal data layout that is fully compatible with the GNU Scientific Library (GSL), and can readily be passed to GSL routines via the C interface. (The Pure interpreter does not require GSL, however, so numeric matrices will work even if GSL is not installed.)

Comprehensions: \([x,y \mid x=1..n; y=1..m; x<y], \{f x \mid x=1..n}\) 

Pure provides both list and matrix comprehensions as a convenient means to construct list and matrix values from a “template” expression and one or more “generator” and “filter” clauses. The former bind a pattern to values drawn from a list or matrix, the latter are just predicates determining which generated elements should actually be added to the result. Comprehensions are in fact just syntactic sugar for a combination of lambdas, conditional expressions and certain list and matrix operations, but they are often much easier to write.

Thus, for instance, \([f x \mid x=1..n]\) is pretty much the same as \(\text{map } f \text{ (1..n)}\), while \([x \mid x=x$s; x>0]\) corresponds to \(\text{filter } (>0) \text{ xs}\). However, comprehensions are considerably more general in that they allow you to draw values from different kinds of aggregates including lists, matrices and strings. Also, matrix comprehensions alternate between row and column generation so that most common mathematical abbreviations carry over quite easily. Patterns can be used on the left-hand side of generator clauses as usual, and will be matched against the actual list or matrix elements; any unmatched elements are filtered out automatically, like in Haskell.

More details and examples can be found in the Examples section; in particular, see List Comprehensions and Matrices and Vectors.

Simple Expressions

The rest of Pure’s expression syntax mostly revolves around the notion of function applications. For convenience, Pure also allows you to declare pre-, post-, out- and infix operator symbols, but these are in fact just syntactic sugar for function applications; see Symbol.
Declarations for details. Function and operator applications are used to combine primary expressions to compound terms, also referred to as simple expressions; these are the data elements which are manipulated by Pure programs.

As in other modern FPLs, function applications are written simply as juxtaposition (i.e., in “curried” form) and associate to the left. This means that in fact all functions only take a single argument. Multi-argument functions are represented as chains of single-argument functions. For instance, in \( f \ x \ y = (f \ x) \ y \) first the function \( f \) is applied to the first argument \( x \), yielding the function \( f \ x \) which in turn gets applied to the second argument \( y \). This makes it possible to derive new functions from existing ones using partial applications which only specify some but not all arguments of a function. For instance, taking the \( \text{max} \) function from the prelude as an example, \( \text{max} \ 0 \) is the function which, for a given \( x \), returns \( x \) itself if it is nonnegative and zero otherwise. This works because \( (\text{max} \ 0) \ x = \text{max} \ 0 \times \) is the maximum of \( 0 \) and \( x \).

One major advantage of having curried function applications is that, without any further ado, functions become first-class objects. That is, they can be passed around freely both as parameters and as function return values. Much of the power of functional programming languages stems from this feature.

Operator applications are written using prefix, postfix, outfix or infix notation, as the declaration of the operator demands, but are just ordinary function applications in disguise. As already mentioned, enclosing an operator in parentheses turns it into an ordinary function symbol, thus \( x+y \) is exactly the same as \( (+) \ x \ y \). For convenience, partial applications of infix operators can also be written using so-called operator sections. A left section takes the form \((x+)\) which is equivalent to the partial application \((+) \ x \). A right section takes the form \((+x)\) and is equivalent to the term \(\text{flip} \ (+) \ x \). (This uses the \(\text{flip} \) combinator from the prelude which is defined as \(\text{flip} \ f \ x \ y = f \ y \ x \).) Thus \((x+)\ y \) is equivalent to \(x+y\), while \((+x)\ y \) reduces to \(y+x\). For instance, \((1/)\) denotes the reciprocal and \((+1)\) the successor function. (Note that, in contrast, \((-x)\) always denotes an application of unary minus; the section \((+\cdot)\) can be used to indicate a function which subtracts \( x \) from its argument.)

The common operator symbols like \(+\), \(-\), \(*\), \(/\) etc. are all declared at the beginning of the prelude, see the Pure Library Manual for a list of these. Arithmetic and relational operators mostly follow C conventions. However, since \(!, \&\) and \(|\) are used for other purposes in Pure, the logical and bitwise operations, as well as the negated equality predicates are named a bit differently: \(\sim\), \&\& and \(||\) denote logical negation, conjunction and disjunction, while the corresponding bitwise operations are named not, and and or. Moreover, following these conventions, inequality is denoted \(\sim\sim\). Also note that \&\& and \(||\) are special forms which are evaluated in short-circuit mode (see Special Forms below), whereas the bitwise connectives receive their arguments using call-by-value, just like the other arithmetic operations.

Special Expressions

Some special notations are provided for conditional expressions as well as anonymous functions (lambdas) and local function and variable definitions. The latter are also called block expressions since they introduce local bindings of variable and function symbols which may override other global or local bindings of these symbols. This gives rise to a kind of block structure similar to Algol-like programming languages. Please check Scoping Rules below
for more information about this.

The constructs described here are called “special” because, in contrast to the other forms of expressions, they cannot occur in normal form terms as first-class values (at least not literally; there is an alternative quoted representation of special expressions, however, which can be manipulated with macros and functions for meta programming purposes, cf. Built-in Macros and Special Expressions).

**Conditional expressions:** if x then y else z

Evaluates to y or z depending on whether x is “true” (i.e., a nonzero integer). A failed_cond exception is raised if the condition is not an integer.

**Lambdas:** \x -> y

These denote anonymous functions and work pretty much like in Haskell. A lambda matches its argument against the left-hand side pattern x and then evaluates the right-hand side body y with the variables in x bound to their corresponding values. Pure supports multiple-argument lambdas (e.g, \x y -> x*y), as well as pattern-matching lambda abstractions such as \((x,y) -> x*y\). A failed_match exception is raised if the actual arguments do not match the given patterns.

**Case expressions:** case x of u = v; ... end

Matches an expression, discriminating over a number of different cases, similar to the Haskell case construct. The expression x is matched in turn against each left-hand side pattern u in the rule list, and the first pattern which matches x gives the value of the entire expression, by evaluating the corresponding right-hand side v with the variables in the pattern bound to their corresponding values. A failed_match exception is raised if the target expression doesn’t match any of the patterns.

**When expressions:** x when u = v; ... end

An alternative way to bind local variables by matching a collection of subject terms against corresponding patterns, similar to Aardappel’s when construct. A single binding x when u = v end is equivalent to the lambda expression \(\lambda u \rightarrow x\) v or the case expression case v of u = x end, so it matches v against the pattern u and evaluates x with the variables in u bound to their corresponding values (or raises a failed_match exception if v doesn’t match u). However, a when clause may contain multiple definitions, which are processed from left to right, so that later definitions may refer to the variables in earlier ones. (This is exactly the same as several nested single definitions, with the first binding being the “outermost” one.)

**With expressions:** x with u = v; ... end

Defines local functions. Like Haskell’s where construct, but it can be used anywhere inside an expression (just like Aardappel’s where, but Pure uses the keyword with which better lines up with case and when). Several functions can be defined in a single with clause, and the definitions can be mutually recursive and consist of as many equations as you want. Local functions are applied in the same way as global ones, i.e., the argument patterns of each rule are matched against the actual function arguments and the first rule which matches has its right-hand side evaluated with the variables in the argument patterns bound to their corresponding values. If none of the rules match then the function application remains unevaluated (it becomes a normal form), so no
exception is raised in this case. (This is in contrast to a lambda which otherwise is pretty much like a nameless local function defined by a single rule.)

The block constructs are similar to those available in most modern functional languages. In Pure these constructs are all implemented in terms of the basic term rewriting machinery, using lambda lifting to eliminate local functions, and the following equivalences which reduce lambdas as well as case and when expressions to special kinds of local functions or local function applications:

\[ \lambda x_1 \ldots x_n \rightarrow y \]
\[ = f \ with \ f \ x_1 \ldots \ x_n = y; f \_ \ldots \_ = \text{throw failed_match end} \]

\[ \text{case } x \ of \ y_1 = z_1; \ldots; y_n = z_n \ end \]
\[ = f \ x \ with \ f \ y_1 = z_1; \ldots; f \ y_n = z_n; f \_ = \text{throw failed_match end} \]

\[ x \ \text{when } y = z \ end \]
\[ = f \ z \ with \ f \ y = x; f \_ = \text{throw failed_match end} \]

\[ x \ \text{when } y_1 = z_1; \ldots; y_n = z_n \ end \]
\[ = x \ \text{when } y_n = z_n \ \text{end} \ldots \ \text{when } y_1 = z_1 \ \text{end} \]

Note that by convention these constructs report a failed_match exception in case of argument mismatch. So they’re treated like defined functions, which is somewhat at odds with the term rewriting semantics. This is done for convenience, however, so that the programmer doesn’t have to deal with unevaluated applications of nameless block constructs in normal form terms. The case of named local functions is considered different because it effectively represents a local rewriting system which should be treated accordingly, in order to allow for symbolic evaluation.

### 1.3.4 Special Forms

As already mentioned, some operations are actually implemented as special forms which process some or all of their arguments using call-by-name.

**if x then y else z**

The conditional expression is a special form with call-by-name arguments y and z; only one of the branches is actually evaluated, depending on the value of x.

\[ x \&\& y \]
\[ x |\| y \]

The logical connectives evaluate their operands in short-circuit mode. Thus the second operand is passed by name and will only be evaluated if the first operand fails to determine the value of the expression. For instance, x&\&y immediately becomes false if x evaluates to false; otherwise y is evaluated to give the value of the expression. The built-in definitions of these operations work as if they were defined by the following equations (but note that the second operand is indeed passed by name):

\[ x::\text{int} \&\& y = \text{if } x \ \text{then } y \ \text{else } x; \]
\[ x::\text{int} |\| y = \text{if } x \ \text{then } x \ \text{else } y; \]

Note that this isn’t quite the same as in C, as the results of these operations are not
normalized, i.e., they may return nonzero values other than 1 to denote “true”. (This has the advantage that these operations can be implemented tail-recursively, see Stack Size and Tail Recursion.) Thus, if you need a normalized truth value then you’ll have to make sure that either both operands are already normalized, or you’ll have to normalize the result yourself. (A quick way to turn a machine int $x$ into a normalized truth value is to compute $-x$ or $x=0$.)

Moreover, if the built-in definition fails because the first operand is not a machine int, then the second operand will be evaluated anyway and the resulting application becomes a normal form, which gives you the opportunity to extend these operations with your own definitions just like the other built-in operations. Note, however, that in this case the operands are effectively passed by value.

$x \mathbin{\&} y$

The sequencing operator $\mathbin{\&}$ evaluates its left operand, immediately throws the result away and then goes on to evaluate the right operand which gives the result of the entire expression. This operator is useful to write imperative-style code such as the following prompt-input interaction:

```
> using system;
> puts "Enter a number:" $\mathbin{\&}$ scanf "%g";
Enter a number:
 21
 21.0
```

We mention in passing here that the same effect can be achieved with a `when` clause, which also allows you to execute a function solely for its side-effects and just ignore the return value:

```
> scanf "%g" when puts "Enter a number:" end;
Enter a number:
 21
 21.0
```

$x \mathbin{\$\$} y$

The sequencing operator $\mathbin{\$\$}$ evaluates its left operand, immediately throws the result away and then goes on to evaluate the right operand which gives the result of the entire expression. This operator is useful to write imperative-style code such as the following prompt-input interaction:

```
> using system;
> puts "Enter a number:" $\mathbin{\$\$}$ scanf "%g";
Enter a number:
 21
 21.0
```

Futures are useful to implement all kinds of lazy data structures in Pure, in particular: lazy lists a.k.a. streams. A stream is simply a list with a thunked tail, which allows it to be infinite. The Pure prelude defines many functions for creating and manipulating these kinds of objects; for further details and examples please Lazy Evaluation and Streams in the Examples section.
This special form quotes an expression, i.e., quote x (or, equivalently, ‘x) returns just x itself without evaluating it. The prelude also provides a function eval which can be used to evaluate a quoted expression at a later time. For instance:

```pure
> let x = '(2*42+2^12); x;
2*42+2^12
> eval x;
4180.0
```

This enables some powerful metaprogramming techniques, which should be well familiar to Lisp programmers. However, there are some notable differences to Lisp’s quote, please see The Quote in the Examples section for details and more examples.

### 1.3.5 Toplevel

At the toplevel, a Pure program basically consists of rewriting rules (which are used to define functions, macros and types), constant and variable definitions, and expressions to be evaluated:

```pure
script ::=  item*
item ::= "let" simple_rule ";;"
      | "const" simple_rule ";;"
      | "def" macro_rule ";;"
      | "type" type_rule ";;"
      | rule ";;"
      | expr ";;"
```

These elements are discussed in more detail in the Rule Syntax section. Also, a few additional toplevel elements are part of the declaration syntax, see Declarations.

```pure
lhs = rhs;
```

Rewriting rules always combine a left-hand side pattern (which must be a simple expression) and a right-hand side (which can be any kind of Pure expression described above). The same format is also used in with, when and case expressions. In toplevel rules, with and case expressions, this basic form can also be augmented with a condition if guard tacked on to the end of the rule, where guard is an integer expression which determines whether the rule is applicable. Moreover, the keyword otherwise may be used to denote an empty guard which is always true (this is syntactic sugar to point out the “default” case of a definition; the interpreter just treats this as a comment). Pure also provides some abbreviations for factoring out common left-hand or right-hand sides in collections of rules; see the Rule Syntax section for details.

```pure
type lhs = rhs;
```

A rule starting with the keyword type defines a type predicate. This works pretty much like an ordinary rewriting rule, except that only a single right-hand side is permitted (which may also be omitted in some cases) and the left-hand side may involve at most one argument expression; see the Type Rules section for details. There’s also an alternative syntax which lets you define types in a more abstract way and have
the compiler generate the type rules for you; this is described in the Interface Types section.

```pure
def lhs = rhs;
```

A rule starting with the keyword `def` defines a macro function. No guards or multiple right-hand sides are permitted here. Macro rules are used to preprocess expressions on the right-hand side of other definitions at compile time, and are typically employed to implement user-defined special forms and simple kinds of optimization rules. See the Macros section below for details and examples.

```pure
let lhs = rhs;
```

Binds every variable in the left-hand side pattern to the corresponding subterm of the right-hand side (after evaluating it). This works like a `when` clause, but serves to bind global variables occurring free on the right-hand side of other function and variable definitions.

```pure
const lhs = rhs;
```

An alternative form of `let` which defines constants rather than variables. (These are not to be confused with nonfix symbols which simply stand for themselves!) Like `let`, this construct binds the variable symbols on the left-hand side to the corresponding values on the right-hand side (after evaluation). The difference is that `const` symbols can only be defined once, and thus their values do not change during program execution. This also allows the compiler to apply some special optimizations such as constant folding.

```pure
expr;
```

A singleton expression at the toplevel, terminated with a semicolon, simply causes the given value to be evaluated (and the result to be printed, when running in interactive mode).

### 1.3.6 Scoping Rules

A few remarks about the scope of identifiers and other symbols are in order here. Special expressions introduce local scopes of functions and variables. Specifically, lambda expressions, as well as the left-hand sides of rules in `case`, `when` and `with` expressions, bind the variables in the patterns to their corresponding values. In addition, a `with` expression also binds function names to the corresponding functions defined by the rules given in the expression. In either case, these bindings are limited to the scope of the corresponding construct. Inside that scope they override other (global or local) definitions of the same symbols which may be present in the surrounding program code. This gives rise to a hierarchical block structure where each occurrence of a symbol refers to the innermost definition of that symbol visible at that point of the program.

The precise scoping rules for the different constructs are as follows:

- \( \lambda x \to y \): The scope of the variables bound by the pattern \( x \) is the lambda body \( y \).
- `case x of u = v; ... end`: The scope of the variables bound by the pattern \( u \) in each rule is the corresponding right-hand side \( v \).
• x when u = v; ... end: The scope of the variables bound by the pattern u in each rule extends over the right-hand sides of all subsequent rules and the target expression x.

• x with u = v; ... end: The scope of the variables bound by the pattern u in each rule is the corresponding right-hand side v. In addition, the scope of the function names defined by the with clause (i.e., the head symbols of the rules) extends over the right-hand sides of all rules and the target expression x. Note that this allows local function definitions to be mutually recursive, since the right-hand side of each rule in the with clause may refer to any other function defined by the with clause.

Like most modern functional languages, Pure uses lexical or static binding for local functions and variables. What this means is that the binding of a local name is completely determined at compile time by the surrounding program text, and does not change as the program is being executed. In particular, if a function returns another (anonymous or local) function, the returned function captures the environment it was created in, i.e., it becomes a (lexical) closure. For instance, the following function, when invoked with a single argument x, returns another function which adds x to its argument:

```pure
> foo x = bar with bar y = x+y end;
> let f = foo 99; f;
bar
> f 10, f 20;
109,119
```

This works the same no matter what other bindings of x may be in effect when the closure is invoked:

```pure
> let x = 77; f 10, (f 20 when x = 88 end);
109,119
```

In contrast to local bindings, Pure’s toplevel environment binds global symbols dynamically, so that the bindings can be changed easily at any time during an interactive session. This is mainly a convenience for interactive usage, but works the same no matter whether the source code is entered interactively or being read from a script, in order to ensure consistent behaviour between interactive and batch mode operation.

In particular, you can easily bind a global variable to a new value by just entering a corresponding let command. For instance, contrast the following with the local bar function from above which had the x value bound in the surrounding context:

```pure
> clear x
> bar y = x+y;
> bar 10, bar 20;
x+10,x+20
> let x = 99;
> bar 10, bar 20;
109,119
> let x = 77;
> bar 10, bar 20;
87,97
```
Observe how changing the value of the global \( x \) variable immediately affects the value computed by the global \( \text{bar} \) function. This works pretty much like global variables in imperative languages, but note that in Pure the value of a global variable can only be changed with a \texttt{let} command at the toplevel. Thus referential transparency is unimpaired; while the value of a global variable may change between different toplevel expressions, it will always take the same value in a single evaluation.

Similarly, you can also add new equations to an existing function at any time. The Pure interpreter will then automatically recompile the function as needed. For instance:

```
> fact 0 = 1;
> fact n::\texttt{int} = n \times \text{fact} (n-1) \texttt{ if } n>0;
> fact 10;
3628800
> fact 10.0;
fact 10.0
> fact 1.0 = 1.0;
> fact n::\texttt{double} = n \times \text{fact} (n-1) \texttt{ if } n>1;
> fact 10.0;
3628800.0
> fact 10;
3628800
```

In interactive mode, it is even possible to completely erase a function definition and redo it from scratch, see section Interactive Usage for details.

So, while the meaning of a local symbol never changes once its definition has been processed, toplevel definitions may well evolve while the program is being processed, and the interpreter will always use the latest definitions at a given point in the source when an expression is evaluated.

**Note:** As already mentioned, this behaviour makes Pure much more convenient to use in an interactive setting. We should point out, however, that dynamic environments are often frowned upon by functional programming purists (for good reasons), and Pure’s dynamic toplevel certainly has its pitfalls just like any other. Specifically, even in a script file you’ll have to take care that all symbols needed in an evaluation are completely defined before entering the expression to be evaluated. Nevertheless, it is expected that most Pure programmers will use Pure interactively most of the time, and so tailoring the design to interactive usage seems justifiable in this case.

### 1.4 Rule Syntax

Basically, the same rule syntax is used in all kinds of global and local definitions. However, some constructs (specifically, \texttt{when}, \texttt{let}, \texttt{const}, \texttt{type} and \texttt{def}) use a variation of the basic rule syntax which does away with guards and/or multiple left-hand or right-hand sides. The syntax of these elements is captured by the following grammar rules:
When matching against a function or macro call, or the subject term in a case expression, the rules are always considered in the order in which they are written, and the first matching rule (whose guard evaluates to a nonzero value, if applicable) is picked. (Again, the when construct is treated differently, because each rule is actually a separate definition.)

### 1.4.1 Patterns

The left-hand side of a rule is a special kind of simple expression, called a pattern. The variables in a pattern serve as placeholders which are bound to corresponding values when the rule is applied to a target expression. To these ends, the pattern is matched against the target expression, i.e., the literal parts of the pattern are compared against the target expression and, if everything matches up, the variables in the pattern are bound to (set to) the corresponding subterms of the target expression.

Patterns are pervasive in Pure; they are used on the left-hand side of function and macro definitions, just as well as in global and local variable definitions. For instance, the following variable definition matches the result of evaluating the right-hand side list expression against the pattern \( x:y:xs \) and binds the variables \( x \) and \( y \) to the first two elements of the resulting list and \( xs \) to the list of remaining elements, respectively. We can then place \( x \) and \( y \) at the end of the list, thereby performing a kind of “rotation” of the first two list members:

```plaintext
> let x:y:xs = 1..10;
> xs+[x,y];
[3,4,5,6,7,8,9,10,1,2]
```

The same works with a local variable definition:

```plaintext
> xs+[x,y] when x:y:xs = 1..10 end;
[3,4,5,6,7,8,9,10,1,2]
```

Or with a case expression:

```plaintext
> case 1..10 of x:y:xs = xs+[x,y] end;
[3,4,5,6,7,8,9,10,1,2]
```

The arguments of functions (and macros) are handled in the same fashion, too:
> rot2 (x:y:xs) = xs+[x,y];
> rot2 (1..10);
[3,4,5,6,7,8,9,10,1,2]

However, there is a big difference here. For global and local variable definitions, it is an error if the pattern does not match the target expression:

> let x:y:xs = [1];
<stdin>, line 7: failed match while evaluating 'let x:y:xs = [1]'

The same holds if the target expression doesn’t match any of the left-hand side patterns in a case expression:

> case [1] of x:y:xs = xs+[x,y] end;
<stdin>, line 8: unhandled exception 'failed_match' while evaluating 'case [1] of x:y:xs = xs+[x,y] end'

(The error message is slightly different in this case, but the reported kind of exception is actually the same as with the let expression above.)

This doesn’t normally happen with functions and macros. Instead, a match failure just means that the corresponding rule will be bypassed and other rules will be tried instead. If there are no more rules, the target expression becomes a normal form which is simply returned as is:

> rot2 [1];
rot2 [1]

This may come as a surprise (other functional languages will give you an error in such cases), but is a crucial feature of term rewriting languages, as it opens the door to symbolic evaluation techniques, see Definitions and Expression Evaluation.

There are two different ways to force a function definition to bail out with an error if you prefer that behaviour. First, you can provide an explicit rule which raises an exception (cf. Exception Handling). But this can make it difficult or even impossible to add more rules to the function later, as discussed below. Instead, you may want to use the --defined pragma as follows:

> #! --defined rot2
> rot2 [1];
<stdin>, line 13: unhandled exception 'failed_match' while evaluating 'rot2 [1]'

**Note:** This pragma tells the compiler that rot2 is supposed to be a “defined” function, which means that it should be an error if no rule applies to it; please see Defined Functions in the Caveats and Notes section for details. Also note that exceptions will always interfere with symbolic evaluation and thus the use of this facility isn’t really recommended. However, there are situations in which it can make your life a lot easier.

One of Pure’s key features is that you can usually just keep on adding new rules to existing function definitions in order to handle different kinds of arguments. As already mentioned,
the rules will then be considered in the order in which they are written, and the first rule which matches the given arguments will be used to reduce the function application. For instance, adding the following rule we can make the \texttt{rot2} function also work with tuples:

\begin{verbatim}
> rot2 (x,y,xs) = xs,x,y;
> rot2 (1,2,3,4,5);
3,4,5,1,2
\end{verbatim}

This is also known as \textbf{ad-hoc polymorphism}. By these means, you can make a function apply to as many different kinds of arguments as you want, and the pattern matching handles the necessary “dispatching” so that the right rule gets invoked for the provided arguments.

Pattern matching is not limited to the predefined aggregates such as lists, tuples and matrices. In principle, any legal Pure expression can occur as a pattern on the left-hand side of a rule or definition, so you can also write something like:

\begin{verbatim}
> rot2 (point x y z) = point z x y;
> rot2 (point 1 2 3);
point 3 1 2
\end{verbatim}

Or even:

\begin{verbatim}
> foo (foo x) = foo x;
> bar (foo x) = foo (bar x);
> foo (bar (foo 99));
foo (bar 99)
\end{verbatim}

Note that symbolic rules like in the latter example (which in this case express the idempotence of \texttt{foo} and a kind of commutativity with respect to \texttt{bar}) often involve symbols which play the role of both a function \textit{and} a constructor symbol.

Syntactically, patterns are simple expressions, thus special expressions need to be parenthesized if you want to include them in a pattern. (In fact, special expressions are given special treatment if they occur in patterns, see the Macros section for details.) A few other special elements in patterns are discussed below.

\textbf{The “Head = Function” Rule}

A central ingredient of all patterns are of course the variables which get bound in the pattern matching process. Pure is a rather terse language and thus it has no explicit way to declare which identifiers are the variables. Instead, the compiler figures them out on its own, using a rather intuitive rule already explained in Variables in Equations.

Recall that the variables in a pattern are the identifiers in “variable positions”. The \texttt{head = function} rule tells us that a variable position is any leaf (atomic subexpression) of the expression tree which is \textit{not} the head symbol of a function application. Thus a pattern like \texttt{f (g x) y} contains the variables \texttt{x} and \texttt{y}, whereas \texttt{f} and \texttt{g} are interpreted as literal function symbols. This rule also applies to the case of infix, prefix or postfix operator symbols, if we write the corresponding application in its unsugared form. E.g., \texttt{x+y*z} is equivalent to \texttt{(+ x (((* y z))} which contains the variables \texttt{x, y} and \texttt{z} and the literal function symbols \texttt{(+) and (**).}
There are some exceptions to the “head = function” rule. Specifically, it is possible to declare an identifier as a nonfix symbol so that it will be interpreted as a literal function symbol even if it occurs in a variable position, see Symbol Declarations for details. For instance:

\[
\text{nonfix nil;}
\]

\[
\text{foo nil = 0;}
\]

Note that since nil is declared as a nonfix symbol here, the symbol is interpreted as a literal rather than a variable in the left-hand side foo nil, and thus foo will return 0 for a literal nil value only.

Another case which needs special consideration are patterns consisting of a single identifier, such as x. Here the meaning depends on the kind of construct. All variable-binding constructs (let, const, when and case) treat a singleton identifier as a variable (unless it is declared nonfix). Thus all of the following constructs will have the expected result of binding the variable x to the given list value \([1,2,3]\). In either case the result is \([0,1,2,3]\):

\[
\text{let x = [1,2,3]; 0:x;}
\]

\[
\text{0:x when x = [1,2,3] end;}
\]

\[
\text{case [1,2,3] of x = 0:x end;}
\]

In contrast, a single identifier is always interpreted as a literal if it occurs on the left-hand side of a function or macro definition, so that the following rule defines a parameterless function y:

\[
y = [1,2,3]; 0:y;
\]

(While they yield the same values here, there are some notable differences between the parameterless function y and the global variable x defined above; see Defining Functions for details.)

Please also check “Head = Function” Pitfalls in the Caveats and Notes section which has some some further interesting details and workarounds concerning the “head = function” rule.

**Constant Patterns**

Constants in patterns must be matched literally. For instance:

\[
\text{foo 0 = 1;}
\]

This will only match an application of foo to the machine integer 0, not 0.0 or 0L (even though these compare equal to 0 using the ‘==’ operator).

**The Anonymous Variable**

The ‘...’ symbol is special in patterns; it denotes the anonymous variable which matches an arbitrary value (independently for all occurrences) without actually binding a variable. This is useful if you don’t care about an argument or one of its components, in which case you can just use the anonymous variable as a placeholder for the value and don’t have to invent a variable name for it. For instance:
foo _ _ = 0;

This will match the application of foo to any combination of two arguments (and just ignore the values of these arguments).

**Non-Linear Patterns and Syntactic Equality**

In contrast to Haskell, patterns may contain repeated variables (other than the anonymous variable), i.e., they may be **non-linear**. Thus rules like the following are legal in Pure, and will only be matched if all occurrences of the same variable in the left-hand side pattern are matched to the same value:

```pure
> foo x x = x;
> foo 1 1;
1
> foo 1 2;
foo 1 2
```

Non-linear patterns are particularly useful for computer algebra where you will frequently encounter rules such as the following:

```pure
> x*y+x*z = x*(y+z);
> a*(3*4)+a*5;
a*17
```

The notion of “sameness” employed here is that of syntactical identity, which means that the matched subterms must be identical in structure and content. The prelude provides syntactic equality as a function `same` and a comparison predicate `===`. Thus the above definition of `foo` is roughly equivalent to the following:

```pure
foo x y = x if same x y;
```

It is important to note the differences between syntactic equality embodied by `same` and `===`, and the “semantic” equality operator `==`. The former are always defined on all terms, whereas `==` is only available on data where it has been defined explicitly, either in the prelude or by the programmer. Also note that `==` may assert that two terms are equal even if they are syntactically different. Consider, e.g.:

```pure
> 0==0.0;
1
> 0===0.0;
0
```

This distinction is actually quite useful. It gives the programmer the flexibility to define `==` in any way that he sees fit, which is consistent with the way the other comparison operators like `<` and `>` are handled in Pure.

Syntactic equality is also used in pattern matching in order to decide whether a constant in a pattern matches the corresponding subterm in the target expression. This explains why the pattern `foo 0`, as already mentioned, only matches an application of `foo` to the machine integer 0, not 0.0 or 0L which aren’t syntactically equal to 0.
However, there is one caveat here. Due to its term rewriting heritage, Pure distinguishes between literal function symbols in patterns and named functions. The latter are runtime objects which are only considered syntactically equal if they not only have the same name but actually refer to the same (global or local) closure. In contrast, a function symbol in a pattern is just a literal symbol without reference to any particular closure that the symbol may be bound to in some context. Thus a function symbol in a pattern matches any instance of the symbol in the target expression, no matter whether it happens to be a pure constructor, quoted symbol or any named closure bound to that symbol.

This leads to some discrepancies between pattern matching and syntactic equality which may be surprising at first sight. For instance, consider:

```>
foo x = case x of bar y = x===bar y end;
> bar x y = x+y;
> foo (bar 99);
1
> foo ('bar 99);
0
> foo (bar 99) with bar x y = x*y end;
0
```

Note that the argument term `bar 99` matches the pattern `bar y` in the `case` expression in either case, even though in the last two expressions `bar` is not considered syntactically equal to the global `bar` function because it is quoted (cf. The Quote) or bound to a local closure of the same name, respectively.

### Special Patterns

Last but not least, patterns may also contain the following special elements which are not permitted in right-hand side expressions:

- A Haskell-style “as” pattern of the form `variable @ pattern` binds the given variable to the expression matched by the subpattern `pattern` (in addition to the variables bound by `pattern` itself). This is convenient if the value matched by the subpattern is to be used on the right-hand side of an equation.

- A left-hand side variable (including the anonymous variable) may be followed by a type tag of the form `:: name`, where `name` is either one of the built-in type symbols `int, bigint, double, string, matrix, pointer`, or an identifier denoting a user-defined data type. The variable can then match only values of the designated type. Thus, for instance, `'x::int'` only matches machine integers. See the Type Tags section below for details.

To these ends, the expression syntax is augmented with the following grammar rule (but note that this form of expression is in fact only allowed on the left-hand side of a rule):

```
prim_expr ::=
  qualified_identifier
  ("::" qualified_identifier | "@" prim_expr)
```

As shown, both “as” patterns and type tags are primary expressions, and the subpattern of
an “as” pattern is a primary expression, too. Thus, if a compound expression is to be used as the subpattern, it must be parenthesized. For instance, the following function duplicates the head element of a list:

```haskell
foo xs@(x:_@) = x:xs;
```

Note that if you accidentally forget the parentheses around the subpattern \( x:_ \), you still get a syntactically correct definition:

```haskell
foo xs@x:_ = x:xs;
```

But this gets parsed as `(foo xs@x):_ = x:xs`, which is most certainly not what you want. It is thus a good idea to just always enclose the subpattern with parentheses in order to prevent such glitches.

**Note:** Another pitfall is that the notation `foo::bar` is also used to denote “qualified symbols” in Pure, cf. Namespaces. Usually this will be resolved correctly, but if `foo` happens to also be a valid namespace then most likely you’ll get an error message about an undeclared symbol. You can always work around this by adding spaces around the `:` symbol, as in `foo:: bar`. Spaces are never permitted in qualified symbols, so this makes it clear that the construct denotes a type tag. The same applies if the variable or the tag is a qualified identifier; in this case they should always be separated by whitespace.

### 1.4.2 Type Tags

Like Lisp, Pure is essentially a typeless language and doesn’t really have a built-in notion of “data types”. Rather, all data belongs to the same universe of terms. However, for convenience it is possible to describe data domains by means of (unary) type predicates which may denote arbitrary sets of terms. The names of these type predicates can then be used as type tags on variables, so that they can only be matched by values of the given type.

We have to emphasize here that Pure’s notion of types has nothing to do with static typing. Type tags are merely used at runtime to restrict the kind of data that can be matched by a rule (and by the compiler to generate better code in some cases). But they will never cause the compiler to impose a static typing discipline and spit out corresponding “type errors”. (This wouldn’t make any sense in Pure anyway, as failure to match any of the rules given in the definition of a function simply means that a function application is in normal form.)

Some basic types are built into the language. The corresponding tags enable you to match the built-in types of terms for which there is no way to spell out all “constructors”, as there are infinitely many (or none, as in the case of pointer values which are constructed and inspected using special primitives, but are otherwise “opaque” at the Pure level). Specifically, the following data types are built-in (in fact, the pattern matcher has special knowledge about these so that they can be matched very efficiently):

```haskell
type int
    The type of machine integers.
```
type bigint
    The type of arbitrary precision integers (GMP bigints).

type double
    The type of double precision floating point numbers.

type string
    The type of character strings.

type matrix
    The type of all numeric and symbolic matrix values.

type pointer
    The type of C pointer values.

Pure’s standard library provides additional data types along with the corresponding operations, such as rational and complex numbers, lists, tuples and the container data types (sets, dictionaries, etc.). These are all described in the Pure Library Manual.

You can define your own data types using a special kind of rule syntax which is explained in Type Rules below. For instance, we might represent points in the plane using a constructor symbol Point which gets applied to pairs of coordinates. We can then define the point data type as follows:

```pure
type point (Point x y);
```

This introduces the type symbol point and specifies that this type consists of terms of the form Point x y. We can now equip this data type with an operation point to construct a point from its coordinates, two operations xcoord and ycoord to retrieve the coordinates, and an operation move to change the coordinates to the given values:

```pure
point x y = Point x y;
xcoord (Point x y) = x;
ycoord (Point x y) = y;
move (Point _ _) x y = Point x y;
```

Next we might define a function translate which shifts the coordinates of a point by a given amount in the x and y directions as follows:

```pure
translate x y p::point = move p (xcoord p+x) (ycoord p+y);
```

Note the use of point as a type tag on the p variable. By these means, we can ensure that the argument is actually an instance of the point data type we just defined. The type tag acts just like an extra guard of the equation defining translate, but all the necessary type checking is done automatically during pattern matching. This is often more convenient (and, depending on the implementation, the compiler may generate more efficient code for a type tag than for an ordinary guard).

The translate function can be invoked as follows:

```pure
> let p::point = point 3 3;
> p; translate 1 2 p;
```
One important point to note here is that translate can be defined without knowing or assuming anything about the internal representation of the point data type. We have defined point as a concrete data type in this example, making its constructor and internal structure visible in the rest of the program. This is often convenient, but the Point constructor might just as well be hidden by making it a private member of some namespace (cf. Namespaces), so that all accesses to the data structure would have to be done through the provided operations. Such a data type is also known as an abstract data type (ADT).

**Note:** As we’ve already seen, Pure has some powerful capabilities which enable you to write functions to inspect and manipulate terms in a completely generic fashion. Thus the internal structure of term data is never truly opaque in Pure and it is always possible to break the “abstraction barrier” provided by an ADT. But if the user of an ADT plays such dirty tricks to wreak havoc on the internal representation of an ADT, he gets what he deserves.

Pure provides some additional facilities to ease the handling of abstract data types. Specifically, instead of defining point as a concrete data type using a type rule, we might also specify it as an interface type which merely lists the supported operations as follows:

```pure
interface point with
  xcoord p::point;
  ycoord p::point;
  move p::point x y;
end;
```

We can implement this type the same way as before:

```pure
point x y = Point x y;
xcoord (Point x y) = x;
ycoord (Point x y) = y;
move (Point _ _) x y = Point x y;
```

The definition of the translate function is also unchanged:

```pure
translate x y p::point = move p (xcoord p+x) (ycoord p+y);
```

The difference is that now the structure of members of the type is not made explicit anywhere in the definition of the type. Instead, the compiler figures out which data matches the point tag on its own. We can check the actual term patterns making up the point type with the show interface command:

```
> show interface point
type point (Point x y);
```

As you can see, the compiler derived our previous definition of the type. But in fact translate will now work with any data type which implements the point interface (i.e., provides the xcoord, ycoord and move operations), so we may swap out the underlying data structure on a whim. For instance, if we’d like to use vectors instead of constructor terms,
all we have to do is to provide a corresponding construction function and implement the interface operations:

```plaintext
vpoint x y = {x,y};
xcoord {x,y} = x;
ycoord {x,y} = y;
move {_,_} x y = {x,y};
```

After these definitions the new data representation works just fine with existing `point` operations such as `translate`:

```plaintext
> show interface point

```

```plaintext
> let p::point = vpoint 3 3;
> p; translate (1,2) p;

```

This separation of interface and implementation of a data structure is an important ingredient of software engineering techniques. More examples and detailed explanations of Pure’s notions of type predicates and interface types can be found in the Type Rules and Interface Types sections.

### 1.4.3 General Rules

The most general type of rule, used in function definitions and `case` expressions, consists of a left-hand side pattern, a right-hand side expression and an optional guard. The left-hand side of a rule can be omitted if it is the same as for the previous rule. This provides a convenient means to write out a collection of equations for the same left-hand side which discriminates over different conditions:

```plaintext
lhs = rhs if guard;
    = rhs if guard;
    ...
    = rhs otherwise;
```

For instance:

```plaintext
fact n = n*fact (n-1) if n>0;
    = 1 otherwise;
```

This expands to:

```plaintext
fact n = n*fact (n-1) if n>0;
    fact n = 1 otherwise;
```

Pure also allows a collection of rules with different left-hand sides but the same right-hand side(s) to be abbreviated as follows:
lhs | ... 
lhs = rhs;

This is useful, e.g., if you specialize a rule to different type tags on the left-hand side variables. For instance:

```
fact n::int | fact n::double = n*fact(n-1) if n>0;  
             = 1 otherwise;
```

This expands to:

```
fact n::int  = n*fact(n-1) if n>0;  
             = 1 otherwise;
fact n::double = n*fact(n-1) if n>0;  
                = 1 otherwise;
```

In fact, the left-hand sides don’t have to be related at all, so you can also write something like:

```
foo x | bar y = x*y;
```

Which expands to:

```
foo x = x*y;
bar y = x*y;
```

But more often you’ll have an “as” pattern which binds a common variable to a parameter value after checking that it matches one of several possible argument patterns (which is slightly more efficient than using an equivalent type-checking guard). E.g., the following definition binds the xs variable to the parameter of foo, which may be either the empty list or a list starting with an integer:

```
foo xs@[] | foo xs@(_:::int:) = bar xs;
```

The | notation also works in case expressions, which is convenient if different cases should be mapped to the same value, e.g.:

```
case ans of "y" | "Y" = 1; _ = 0; end;
```

Sometimes it is useful if local definitions (when and with) can be shared by the right-hand side and the guard of a rule. This can be done by placing the local definitions behind the guard, as follows (we only show the case of a single when clause here, but of course there may be any number of when and with clauses behind the guard):

```
lhs = rhs if guard when defs end;
```

Note that this is different from the following, which indicates that the definitions only apply to the guard but not the right-hand side of the rule:
\text{lhs} = \text{rhs} \text{ if (guard when defns end);} \\

Conversely, definitions placed \textit{before} the guard only apply to the right-hand side but not the guard (no parentheses are required in this case):

\text{lhs} = \text{rhs when defns end if guard;}

An example showing the use of a local variable binding spanning both the right-hand side and the guard of a rule is the following quadratic equation solver, which returns the (real) solutions of the equation \(x^2+p\cdot x + q = 0\) if the discriminant \(d = p^2/4 - q\) is nonnegative:

\begin{verbatim}
> using math;
> solve p q = -p/2+sqrt d,-p/2-sqrt d if d>=0 when d = p^2/4-q end;
> solve 4 2; solve 2 4;

-0.585786437626905,-3.41421356237309

solve 2 4
\end{verbatim}

Note that the above definition leaves the case of a negative discriminant undefined.

1.4.4 Simple Rules

As already mentioned, \textit{when}, \textit{let} and \textit{const} use a simplified kind of rule syntax which just consists of a left-hand and a right-hand side separated by the equals sign. In this case the meaning of the rule is to bind the variables in the left-hand side of the rule to the corresponding subterms of the value of the right-hand side. This is also called a \textbf{pattern binding}.

Guards or multiple left-hand or right-hand sides are not permitted in these rules. However, it is possible to omit the left-hand side if it is just the anonymous variable ‘\_’ by itself, indicating that you don’t care about the result. The right-hand side is still evaluated, if only for its side-effects, which is handy, e.g., for adding debugging statements to your code. For instance, here is a variation of the quadratic equation solver which also prints the discriminant after it has been computed:

\begin{verbatim}
> using math, system;
> solve p q = -p/2+sqrt d,-p/2-sqrt d if d>=0 when d = p^2/4-q end;
> when d = p^2/4-q; printf "The discriminant is: %g\n" d; end;
> solve 4 2;

The discriminant is: 2
-0.585786437626905,-3.41421356237309

solve 2 4;

The discriminant is: -3
solve 2 4
\end{verbatim}

Note that simple rules of the same form \texttt{lhs = rhs} are also used in macro definitions (\texttt{def}), to be discussed in the \texttt{Macros} section. In this case, however, the rule denotes a real rewriting rule, not a pattern binding, hence the left-hand side is mandatory in these rules.

1.4.5 Type Rules

In Pure the definition of a type takes a somewhat unusual form, since it is not a static declaration of the structure of the type’s members, but rather an arbitrary predicate which de-
terminates through a runtime check which terms belong to the type. Thus the definition of a type looks more like an ordinary function definition (and that’s essentially what it is, although types live in their own space where they can’t be confused with functions of the same name).

The definition of a type thus consists of one or more type rules which basically have the same format as the general rules, but with the keyword type in front of each rule. Also, each left-hand side must have at most one argument pattern and exactly one right-hand side. Hence, if the definition of a type requires several right-hand sides, you normally have to write a separate type rule for each of them. Multiple left-hand sides work the same as in the general rule format, though.

As already mentioned, there is an alternative way for defining types in an indirect way through so-called interface types from which the corresponding type rules are derived automatically. These are part of Pure’s declaration syntax and thus will be discussed later in the Declarations section. In this section we focus on how you can write your own type rules in order to define types in a direct fashion.

The identifier in the head of the left-hand side of a type rule is the name of the type which can then be used as a type tag in other equations, cf. Type Tags. This is just a normal, possibly qualified identifier subject to the same namespace mechanisms as other symbols; see Namespaces for details. However, as the type symbol only gets used as a type tag, it can never collide with function and variable symbols and hence the same symbol can be used both as a type and as a function or variable name.

A collection of type rules specifies a predicate, i.e. a unary, truth-valued function which denotes a set of terms. The type consists precisely of those terms for which the type predicate yields a nonzero result. For instance, the following type defines the type triple as the set of all tuples with exactly three elements:

\[
\text{type } \text{triple} (x,y,z) = \neg \text{tuplep } z;
\]

Note that the type check consists of two parts here: The left-hand side pattern \((x,y,z)\) restricts the set to all tuples with at least three elements. The right-hand side \(\neg \text{tuplep } z\) then verifies that the last component \(z\) is not a tuple itself, and thus the entire tuple consists of exactly three elements.

Another important point here is that the definition of the triple predicate is partial, as the given rule only applies to tuples with at least three elements. A value will only match the triple type tag if the predicate explicitly returns true; otherwise the match will fail, no matter what the result is (and even if the predicates just fails, i.e., returns an unevaluated normal form). Thus there is no need to make the predicate work on all terms (and in fact there are good reasons to not do so, see below).

In general, you should try to make your type definitions as specific as possible. This makes it possible to extend the predicate later, just like Pure allows you to extend the definition of a function to new types of arguments. For instance, if you later decide that lists with three elements should be considered as triples, too, then you may add the following type rule:
type triple [x, y, z] = true;

This makes it possible to define a type in a piecemeal fashion. Each subsequent rule enlarges
the term set of the type. Conversely, consider a definition like:

type pair x = tuplep x & & #x==2;

In this case the type rule applies to all values x and thus the type definition is complete; there
is no way to extend it later. Whether to prefer the former or latter kind of definition depends
on the situation. If you want to keep a type extensible, so that you can later make existing
definitions of operations on the type work with new data representations, then you should
use the former approach, otherwise the latter.

As an example for an extensible type definition, consider the following type nat which de-
notes the type of positive (machine) integers:

type nat x::int = x>0;

This definition is complete for the case of machine integers, but allows the type to be ex-
tended for other base types, and we’ll do that in a moment. But first let’s define the factorial
on nat values as follows:

fact n::nat = if n==1 then 1 else n * fact (n-1);

Note that this definition would loop on zero or negative values if we permitted arbitrary int
arguments. But since we restricted the argument type to nat, this case cannot occur and so
the definition is safe:

> fact 0;
fact 0
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]

The way we defined fact, it works on positive machine integers, but nothing else:

> fact 10L;
fact 10L

If we later decide that positive bigints should be considered as members of nat as well, we
can simply add another rule for the nat type:

type nat x::bigint = x>0;

Et voila, our fact routine now magically works with bigints, too:

> map fact (0L..10L);
[fact 0L,1L,2L,6L,24L,120L,720L,5040L,40320L,362880L,3628800L]

Note that we did all this without ever touching our original definition of fact. This works
because the bigint data type already provides all the operations which we expect to use
with the nat type. Pulling off this trick with other, more exotic kinds of data requires more
preparation, since we’ll first have to provide the required operations. In this case, we need
at least multiplication, as well as comparisons with 1 and subtraction by 1. For instance, and just for the fun of it, let’s implement our own variation of the nat type using Peano arithmetic:

```haskell
type nat (s x) = true;

// addition
x + 0 = x;
x + 1 = s x;
x + s y = s (x+y);

// multiplication
x * 0 = 0;
x * 1 = x;
x * s y = x + x*y;

// subtract 1
s x - 1 = x;

// comparison with 0 and 1
s x == 0 = false;
s x == 1 = x == 0;
```

This implements just the bare bones, but that should be enough to make fact work. Let’s give it a try:

```haskell
> fact (s (s (s 0)));
s (s (s (s (s (s 0)))))
```

So, counting the s’s, the factorial of 3 is 6. Works! (It goes without saying, though, that this implementation of nat is not very practical; you’ll get mountains of s’s for larger values of n.)

As you can see, a type definition may in general consist of many type rules which may be scattered out over different parts of a program. This works in exactly the same way as with ordinary functions.

There’s an additional convenience provided for type rules, namely that the right-hand side may be omitted if it’s just true. For instance, the rule

```haskell
type nat (s x) = true;
```

from above can also be written simply as:

```haskell
type nat (s x);
```

This kind of notation is particularly convenient for “algebraic types” which are usually given by a collection of constructors with different arities. For instance, a binary tree data type might be defined as follows (here we employ the | symbol to separate the different left-hand sides so that we can give all the constructor patterns in one go):

1.4.5 Type Rules
nonfix nil;

\texttt{type} bintree nil | bintree (bin x left right);

This method is also useful if you define your own abstract data types. In this case you’re free to choose any suitable representation, so you might just wrap up all data objects of the type with a special constructor symbol, which makes checking the type simple and efficient. This is also the approach taken in the \texttt{point} example in \texttt{Type Tags} above, as well as by the container data types in the standard library.

The same notation can also be used to quickly make one type a “subtype” of another, or to create a type which is the union of several existing types. The following example can be found in the standard library:

\begin{verbatim}
\texttt{type} integer x::\texttt{int} | integer x::\texttt{bigint};
\end{verbatim}

A type rule can also take the form of a function definition without arguments. The corresponding right-hand side may either be another type symbol, or any kind of closure denoting a (curried) type predicate. In this case the defined type is simply an \texttt{alias} for the type denoted on the right-hand side. This is often done, e.g., for numeric types, to document that they actually stand for special kinds of quantities:

\begin{verbatim}
\texttt{type} speed = double;
\texttt{type} size = int;
\end{verbatim}

Note that the definition of a type alias is always complete; there’s no way to extend the corresponding type later. Therefore type aliases are normally resolved at compile time, so that they incur no additional runtime cost. For instance:

\begin{verbatim}
> half x::speed = x/2;
> show half
half x::\texttt{double} = x/2;
\end{verbatim}

(If necessary, this “type folding” can also be disabled with the \texttt{--nofold} pragma.)

Finally, it’s also possible to just specify the type name, without giving the right-hand side:

\begin{verbatim}
\texttt{type} thing;
\end{verbatim}

This doesn’t have any effect other than just declaring the type symbol, so that it can be used as a type tag in subsequent definitions. You then still have to give a proper definition of the type later (either as an explicit predicate or an alias).

Type aliases can also be used to quickly turn an existing predicate into a “convenience” type which can be used as a tag on the left-hand side of equations. The prelude defines a number of these, see \texttt{Prelude Types}. For instance:

\begin{verbatim}
\texttt{type} closure = closurep;
\end{verbatim}

Conversely, you can turn any type tag into an ordinary predicate which can be used on the right-hand side of other definitions. To these ends, the prelude provides the \texttt{typep} predicate which takes a type symbol and the value to be checked as arguments. For instance:
type odd x::int = x mod 2;
type even x::int = ~odd x;

odd x = typep odd x;
even x = typep even x;

With those definitions you get:

> map odd (0..10);
[0,1,0,1,0,1,0,1,0,1,0]
> map even (0..10);
[1,0,1,0,1,0,1,0,1,0,1]

There’s one caveat here. As the type symbol passed to typep gets evaluated in normal code
you have to be careful if the symbol is also defined as a parameterless function or a variable;
in such a case you’ll have to quote the symbol, as described in section The Quote. For in-
stance, we might rewrite the above definitions as follows, giving “pointless” definitions of
the odd and even predicates in terms of typep:

    type odd x::int = x mod 2;
    type even x::int = ~odd x;

    odd = typep ('odd);
    even = typep ('even);

Note that the quotes on odd and even are really needed here to prevent the predicate defi-
nitions from looping. If you need this a lot then you might define a little helper macro (cf.
Macros) which quotes the type symbol in an automatic fashion:

def typep ty::symbol = typep ('ty);

(However, this gets in the way if you want to check for computed type symbols, that’s why
this macro isn’t defined in the prelude.)

Pure places no a priori restrictions on the rules defining a data type (other than that they
must either define a unary predicate or an alias for an existing data type). As far as Pure is
concerned, types are just subsets of the universe of terms. Thus any type of relation between
two data types is possible; they might be unrelated (disjoint) term sets, one may be a subset
of another, or they might be related in some other way (some terms may be members of both
types, while others aren’t).

For instance, consider the types nat and odd from above. Both are subtypes of the int type
(assuming our original definition of nat as the positive int values), but neither is a sub-
type of the other. It’s sometimes useful to define the “intersection type” of two such types,
which can be done in a straightforward way using the logical conjunction of the two type
predicates:

    type nat x::int = x>0;
    type odd x::int = x mod 2;
    type odd_nat x = typep nat x && typep odd x;
Similarly, a variation of the integer union type from above could be defined using logical disjunction (this employs the `intp` and `bigintp` predicates from the prelude):

```pure
type myinteger x = intp x || bigintp x;
```

(Note that this isn’t quite the same as the previous definition, which uses explicit patterns in order to make the definition extensible.)

Since the right-hand side of a type definition may in general be any predicate, it is up to the programmer to ensure that the definition of a type is actually computable. In fact, you should strive for the best possible efficiency in type predicates. A type definition which has worse than $O(1)$ complexity may well be a serious performance hog depending on the way in which it is used, see Recursive Types in the Caveats and Notes section for more information about this.

Finally, note that in general it may be hard or even impossible to predict exactly when the code of a type definition will be executed at runtime. Thus, as a general rule, a type definition should not rely on side effects such as doing I/O (except maybe for debugging purposes), modifying references or external data structures via C pointers, etc.

### 1.5 Examples

This section assumes that you’ve read the Pure Overview and Rule Syntax sections, so that you are familiar with the basic elements of the Pure language. We now bring the pieces together and show you how simple but typical problems can be solved using Pure. You might use this section as a mini-tutorial on the Pure language. As we haven’t discussed the more advanced elements of the Pure language yet, the scope of this section is necessarily limited. But it should give you a pretty good idea of how Pure programs looks like. After working through these examples you should be able to write useful Pure programs and understand the more advanced features discussed in subsequent sections.

#### 1.5.1 Hello, World

The notorious “hello world” program can be written in Pure as follows:

```pure
using system;
puts "Hello, world!";
```

This employs the `puts` function from Pure’s system module (which is in fact just the `puts` function from the C library). If you put these lines into a script file, say, `hello.pure`, you can run the program from the command line as follows:

```
$ pure hello.pure
Hello, world!
```

You may notice a slight delay when executing the script, before the “Hello, world!” message appears. That’s because the interpreter first has to compile the definitions in your script as well as the prelude and other imported modules before the `puts "Hello, world!"` expression can be evaluated. The startup times can be reduced (sometimes considerably) by compiling scripts to native executables, see Compiled Scripts below.
Passing Parameters

Sometimes you may want to pass parameters to a script from the command line. To these ends, just follow the script name with the required parameters. The interpreter makes the command line parameters (including the script name) available as a list of strings in the \texttt{argv} variable. For instance, here is a version of the “hello world” program which uses \texttt{printf} to print the line \texttt{Hello, foo!} where \texttt{foo} is whatever was specified as the first command line parameter:

\begin{verbatim}
using system;
printf "Hello, %s!\n" (argv!1);
\end{verbatim}

This script is invoked as:

\begin{verbatim}
$ pure hello.pure foo
Hello, foo!
\end{verbatim}

Of course, many real-world programs will require more elaborate processing of command line parameters, such as recognizing program options. We won’t discuss this here, but you can have a look at the \texttt{getopt} module which provides that kind of functionality in a convenient package.

Executable Scripts

It is often convenient if you can turn a script into a standalone executable which can be invoked by just typing its name on the command line. There are several ways to do this.

First, on most systems you can invoke the Pure script through some kind of shell script or command file which contains the command to invoke the interpreter. The details of this depend on the operating system and type of shell that you use, however, so we won’t go into this here.

Second, on Unix-like systems it is possible to make any script file executable like this:

\begin{verbatim}
$ chmod a+x hello.pure
\end{verbatim}

However, we also have to tell the shell about the command interpreter which should be invoked to run the script. (Otherwise the shell itself may try to execute the script, which won’t work because it’s not a shell script.) As already mentioned in Overview of Operation, this is done by adding a special kind of comment, a “shebang”, to the beginning of the script, so that it looks like:

\begin{verbatim}
#!/usr/local/bin/pure
using system;
puts "Hello, world!";
\end{verbatim}

Note that you \texttt{must} give the full path to the Pure interpreter in the shebang line. This path of course depends on where you installed Pure. The above shebang will work with an installation from source, unless you changed the installation prefix when configuring the source package. If you installed the interpreter from a binary package, the proper path will often be
Pure Language and Library Documentation, Release 0.68

/usr/bin/pure instead. In any case, you can find out where the interpreter lives by typing
the following command in the shell:

```
$ which pure
/usr/local/bin/pure
```

If you get anything else on your system then you’ll have to fix the shebang accordingly. You
should then be able to run the script as follows:

```
$ ./hello.pure
Hello, world!
```

Note: Many modern Unix-like systems provide the /usr/bin/env utility which can perform
a search for the interpreter executable, so that you can also use a shebang like:

```
#!/usr/bin/env pure
```

This has the advantage that you don’t have to hardcode the path to the Pure interpreter into
the shebang; the /usr/bin/env utility will locate the interpreter for you, provided that it is
installed somewhere on the system PATH.

Compiled Scripts

Last but not least, you can also turn a Pure script into an executable by “batch-compiling” it.
This works on all supported systems (provided that you have the necessary LLVM tools and
3rd party compilers installed, see the installation instructions for details). The result is a real
native executable which can then be run directly just like any other binary program on your
system. To these ends, the interpreter is run with the -c option which tells it to run in batch
compilation mode, and the -o option which specifies the desired name of the executable. For
instance:

```
$ pure -c hello.pure -o hello
$ ./hello
Hello, world!
```

We should mention here that batch-compiled scripts have some limitations. In particular,
some of the advanced compile time features are only available when running a script with
the interpreter. However, this won’t affect run-of-the-mill scripts like the one above. More
information can be found in the Batch Compilation section.

1.5.2 Running the Interpreter

While Pure scripts can be run as standalone programs directly from the shell, most of the
time you’ll probably use the Pure interpreter in an interactive way. You then simply run it
like this:

```
$ pure
  -- \  | | --| -- \ Pure 0.68 (x86_64-unknown-linux-gnu)
```

1.5 Examples
The interpreter prints its sign-on message and leaves you at its command prompt. (You can also try `pure --plain` for a less fancy sign-on, or `pure -q` to completely suppress the message.)

At this point you can just start typing definitions and expressions to be evaluated. For instance:

```
> fact n = if n<=0 then 1 else n*fact (n-1);
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

Note that Pure is a free-format language, and thus definitions and expressions **must** be terminated with a semicolon, so that the interpreter knows when you’re done entering each item. This probably needs getting used to, but it’s convenient because you can easily type more than one expression on a single line, or split longer constructs across multiple lines:

```
> 6*7; 16.3805*5.0;
42
81.9025
> 16753418726345
> * 99172653425671826524;
166148098904297299930396098173389730L
```

If the interpreter appears to just eat away expressions without printing any results, then most likely you forgot to enter the terminating semicolon. In such a case you can just type the semicolon on a line by itself:

```
> 6*7
>
```

(This won’t do any harm even if it’s not needed, because an empty item is always valid input at Pure’s toplevel.)

The interpreter also reports syntax errors if you mistype an expression:

```
> 16.3805*(5;
<stdin>, line 8: syntax error, unexpected ';', expecting when or with or ')
```

In such a case, just correct the error and resubmit the offending input. The interpreter’s readline facility makes this pretty convenient, because you can use the cursor keys to recall previous input lines and edit them as needed.

Other kinds of errors may happen at runtime, when evaluating a syntactically correct expression. These give rise to so-called exceptions. For instance:
> 1 div 0;
<stdin>, line 9: unhandled exception ‘signal 8’ while evaluating ‘1 div 0’

Besides integer division by zero (flagged as ‘signal 8’ here), common sources of exceptions are failed matches and conditionals, interrupts (e.g., if the user aborts an evaluation with Ctrl-c) and stack overflows (cf. Stack Size and Tail Recursion). Normally these are fatal and require you to fix the program or the expression that you entered, but programs can also catch these errors and handle them in any desired way, cf. Exception Handling.

Note that in contrast to most other programming languages, undefined identifiers are generally not an error in Pure. Instead, you’ll simply get an unevaluated normal form:

> foo 5;
foo 5

Therefore, we recommend invoking the interpreter with the -w option so that it at least warns you about unknown symbols. You can also enter this option interactively or in a script using the --warn pragma:

> #! --warn
> bar 5;
<stdin>, line 12: warning: implicit declaration of ‘bar’
bar 5

The interpreter has a global variable environment in which you can store intermediate results:

> let x = 16.3805*5;
> x; x/2; 1/x;
81.9025
40.95125
0.0122096395103935
> let y = 2*x; y;
163.805

Another handy feature is the special built-in function ans which yields the most recent result printed by the interpreter:

> 16.3805*5;
81.9025
> ans*2;
163.805

The interpreter recognizes a few other special commands which, like ans, are only available when it is run interactively. For instance, you can purge the value of a variable like this (this also works with any other defined item, such as constants, functions and macros):

> clear x
> x;
x

Another useful command is show which prints the definition of anything that you can define in a Pure script, such as variables and functions. For instance:
Pure Language and Library Documentation, Release 0.68

> show fact
fact n = if n<=0 then 1 else n*fact (n-1);

You can also just type show to print all definitions done interactively at the command prompt, which lets us review our accomplishments so far:

> show
fact n = if n<=0 then 1 else n*fact (n-1);
let y = 163.805;

The dump command saves these definitions in a file for later use:

> dump

This command doesn’t print anything, but you can have a look at the written file in a text editor and maybe edit it as needed. By default, dump saves interactive definitions in a hidden file named .pure in the current directory, which gets reloaded automatically if we later rerun the interpreter in the same directory. We can also print this file, e.g., with the Unix cat command (note that ‘!’ executes a shell command):

> !cat .pure
// dump written Wed Sep 5 10:00:15 2012
fact n = if n<=0 then 1 else n*fact (n-1);
let y = 163.805;

If we mess up badly, it’s often convenient to just rerun the interpreter from scratch so that we can try again in a clean environment:

> run

As we’ve saved our scribblings with dump previously, those definitions will be reloaded automatically:

> show
fact n = if n<=0 then 1 else n*fact (n-1);
let y = 163.805;

If you don’t want this then you can just remove the .pure file or rename it before invoking run.

Another helpful command is help which brings up the online documentation (this requires that you’ve configured the interpreter for the web browser that you use; see Online Help):

> help help

Last but not least, you can use the following command to exit the interpreter and return to the command shell:

> quit

Typing just an end-of-file character (usually Ctrl-d on Unix-like systems) at the beginning of the command line does the same.
There are a few other built-in commands that you may find useful when working with the interpreter, and you can even define your own. These interactive commands are special; they have their own syntax and need to be typed on a separate line. Please refer to Interactive Usage for a detailed explanation of the command syntax and the available commands.

### 1.5.3 Basic Examples

Pure has a few built-in data types, namely numbers (machine integers, bigints and double precision floating point numbers), strings, matrices, symbols, functions and pointer values. Compound expressions are formed from these using function application. In the syntax of the Pure language, these are also known as simple expressions. For want of a catchier name, we also simply call them terms. Pure is a programming language based on term rewriting, so all computations performed in Pure consist of the rewriting of terms. Some terms may reduce to other terms, others simply stand for themselves; the latter are also called normal forms and are what constitutes a “value” in the Pure language.

When the Pure interpreter starts up, it normally loads a collection of Pure scripts collectively called the prelude. The prelude defines many of the usual operations on numbers, strings, lists and other basic data structures that you may need, so you can start using the interpreter as a sophisticated kind of desktop calculator right away. Let’s begin with some simple calculations involving integer and floating point numbers:

```plaintext
> 6*7;
42
> 16.3805*5.0;
81.9025
> 16753418726345 * 991726534256718265234;
1661480989042972993039698173389730L
```

Note that the integer constants in the last example exceeded the 32 bit range of machine integers, so they were promoted to bigints. The result is again a bigint (indicated by the L suffix). You can also turn any integer constant into a bigint by explicitly adding the L suffix:

```plaintext
> 6L*7L;
42L
```

Arithmetic with mixed operands will generally return the most general type capable of holding the result:

```plaintext
> 6*7L;
42L
> 16.3805*5;
81.9025
> 16.3805*5L;
81.9025
```

But note that most operations involving only machine integers will produce another machine integer; the result is never promoted to a bigint automatically, even in case of “overflow” (i.e., wrap-around). So the following will yield the same kind of signed 32 bit result as you’d get in C:
This has the advantage that you always know the type of the result of each operation beforehand by just looking at the types of the operands. It also makes it possible to compile machine integer operations to efficient native code. Therefore, if you suspect that a machine integer operation may wrap around and you’d thus prefer to do the calculation with bigints instead, you’ll have to convert at least one of the operands to a bigint beforehand:

```pure
> 2147483647L + 1;
2147483648L
```

Also note that, in contrast to C or Fortran, the result of the `/` (division) and `^` (exponentiation) operators is always a floating point value in Pure, even if both operands are integers:

```pure
> 14/12;
1.16666666666667
> 2L^60L;
1.15292150460685e+18
```

Integer division and modulo are done with the `div` and `mod` operators, and exact powers of machine integers and bigints can be computed with the `pow` function:

```pure
> 14 div 12; 14 mod 12;
1 2
> pow 2 60;
1152921504606846976L
```

Also note that many of the standard math functions are available in a separate `math` module, so we need to import that module if we want to use one of these (see Modules and Imports for a detailed explanation of Pure’s module system). For instance:

```pure
> using math;
> sqrt (16.3805*5)/.05;
181.0
```

The `math` module also provides you with complex and rational number types for doing more advanced calculations, but we won’t go into that here.

Before we proceed, a few remarks about the syntax of function applications are in order. Function application is an explicit operation in Pure, so that functions become first class values which can be passed around as function arguments and results. Like in most modern functional languages, function application is simply denoted by juxtaposition:

```pure
> sqrt 2;
1.4142135623731
```

In this case, you may also write `sqrt(2)` instead, but multiple arguments are normally specified as `f x y z` rather than `f(x,y,z)`. The former notation is known as currying (named after the American mathematician and logician Haskell B. Curry), and is ubiquitous in modern functional programming languages. The latter notation can be used in Pure as well, but
it actually indicates that $f$ is called on a *single*, structured argument (in this case a tuple). However, most predefined functions use the curried notation in Pure. For instance, the `max` function defined in the prelude takes two separate arguments, so it is invoked as follows:

```plaintext
> max 4 7;
7
```

Function application associates to the left, so the above is parsed as `(max 4) 7`, where `max 4` is called a **partial application** of the `max` function. A partial application is a function in its own right; e.g., `max 4` denotes the function which computes `max 4 y` for each given `y`.

Parentheses are used for grouping expressions as usual. In particular, since function application associates to the left, a nested function application in a function argument must be parenthesized as follows:

```plaintext
> sqrt (sqrt 2);
1.18920711500272
```

The same is true for any kind of expression involving operators, since function application binds stronger than any of these:

```plaintext
> sqrt (2*3);
2.44948974278318
```

The `map` function lets us apply a function to each member of a given list, which gives us a quick way of tabulating function values:

```plaintext
> map sqrt (0..2);
[0.0,1.0,1.4142135623731]
```

Here, the list argument is specified as an **arithmetic sequence** `0..2` which evaluates to the list `[0,1,2]`. This is fairly convenient when tabulating values of numeric functions. Here is another example which employs a partial application of the `max` function as the function argument:

```plaintext
> map (max 0) (-3..3);
[0,0,0,1,2,3]
```

Note that when the `max 0` function gets applied, say, to the first list member `-3`, we obtain the application `max 0 (-3)` which now has all the arguments that it needs; we also say that `max 0 (-3)` is a **saturated** application, which means that it’s “ready to go”. Evaluating `max 0 (-3)` gives `0` which becomes the first member of the result list returned by `map`. The other list members are calculated in an analogous fashion. It is easy to see that `max 0` thus computes what mathematicians call the “positive part” of its argument $x$, which is $x$ itself if it is greater than $0$ and $0$ otherwise.

Operators aren’t special either, they are just functions in disguise. You can turn any operator into an ordinary function by enclosing it in parentheses. Thus `(+)` denotes the function which adds its two arguments, and $x+1$ can also be written as `(+) x 1$; in fact, the former expression is nothing but syntactic sugar for the latter. You can easily verify this in the interpreter:
You can also have partial applications of operators like \((\ast) \ 2\) which denotes a function which doubles its argument:

\[
\text{map } (\ast) \ 2 \ [1,2,3,4,5]; \\
[2,4,6,8,10]
\]

Moreover, Pure offers some convenient syntactic sugar to denote so-called \textbf{operator sections} which specify a binary operator with only either its left or right operand. So the doubling function above may also be denoted as \((2\ast)\) or \((\ast2)\). Similarly, \((+1)\) denotes the “increment by 1” and \((1/)\) the reciprocal function:

\[
\text{map } (+1) \ (1..5); \\
[2,3,4,5,6] \\
\text{map } (1/) \ (1..5); \\
[1.0,0.5,0.333333333333333,0.25,0.2]
\]

Note that the latter kind of section (also called a \textbf{left section}) is just a convenient shorthand for a partial application:

\[
> \ (1/); \\
(1) \ 1
\]

The former kind (a \textbf{right section}) can’t be handled this way, because it’s the first operand which is missing, and partial applications only allow you to omit trailing arguments. Instead, right sections expand to a partial application of the \textbf{flip} function,

\[
> \ (+1); \\
\text{flip } (+) \ 1
\]

which is defined in the prelude as follows:

\[
\text{flip } f \ x \ y = f \ y \ x;
\]

Note that \text{flip } (+) \ 1 thus denotes a function which, when the missing operand is supplied, reduces to an application of the first (function) argument while also flipping around the operands. For another example, here’s how you can compute third powers \(x^3\) of some numbers \(x\) with a right section of the \(^3\) operator:

\[
> \text{map } (^3) \ (1..5); \\
[1.0,8.0,27.0,64.0,125.0]
\]

Note that this is exactly the same as:

\[
> \text{map } (\text{flip } ^3) \ (1..5); \\
[1.0,8.0,27.0,64.0,125.0]
\]

Such explicit applications of \text{flip} also work with ordinary functions like \text{pow}, so if we want to compute the cubes as exact bigint numbers, we can also write:
> map (flip pow 3) (1..5);
[1L,8L,27L,64L,125L]

Note the difference between flip pow 3 which computes third powers, and pow 3 which is a partial application that computes powers of 3.

Sometimes it is convenient to have function application as an explicit operation which can be passed as a function value to other functions. The $ operator is provided for this purpose. f $ x is just f x, so you can write, e.g.:

> map ($1) [(+2),(*2),(/2)];
[3,2,0.5]

Recall that ($1) is a right section which, when applied to an argument f, evaluates to f $ 1 = f 1. E.g., we have that ($1) (+2) = (+2) $ 1 = (+2) 1 = 1+2 = 3. Hence the above expression actually applies a list of functions to the given argument 1.

The $ operator has a low precedence and is right-associative, so that it is sometimes used to eliminate the parentheses in cascading function calls. For instance, sqrt $ sqrt $ 2+3 is the same as sqrt (sqrt (2+3)).

Another convenient operation for combining functions is the function composition operator, denoted ‘.’. It applies two functions in sequence, so that (f . g) x evaluates to f (g x). For instance:

> g x = 2*x-1;
> map g (-3..3);
[-7,-5,-3,-1,1,3,5]
> map (max 0 . g) (-3..3);
[0,0,0,0,1,3,5]

Operations like ‘.’, which take functions as arguments and return other functions as results, are also called higher-order functions. We’ll have a closer look at these later.

As already mentioned, the interpreter also has a global variable environment in which you can store arbitrary expression values. This provides a means to define abbreviations for frequently-used expressions and for storing intermediate results. Global variable definitions are done with let. For instance:

> let x = 16.3805*5;
> x;
81.9025

As we’ve explained above, functions are first-class citizens and can thus be assigned to variables as well:

> let f = sqrt;
> f x/0.05;
181.0

The value of a global variable can be changed at any time. So we can type:
Pure Language and Library Documentation, Release 0.68

> let f = sin;
> f x/0.05;
4.38588407225469

You can also bind several variables at once by using an expression pattern as the left-hand side of a variable definition. This is useful if we need to extract elements from an aggregate value such as a list:

> let x1:x2:xs = map (^3) (1..5);
> x1,x2,xs;
1.0,8.0,[27.0,64.0,125.0]

Pure also provides a kind of “read-only” variables a.k.a. constants. They are defined pretty much like global variables (using the const keyword in lieu of let), but work more like a parameterless function whose value is precomputed at compile time:

> const π = 4*atan 1.0;
> show π
const π = 3.14159265358979;
> h x = sin (2*π*x);
> show h
h x = sin (6.28318530717959*x);
> map h [-1/4,-1/8,0,1/8,1/4];
[-1.0,-0.707106781186547,0.0,0.707106781186547,1.0]

Note that the compiler normally computes constant subexpressions at compile time, such as $2\pi$ in the function h. This works with all simple scalars (machine ints and doubles), see Constant Definitions for details.

As an aside, the last example also shows that Pure has no problems with Unicode. π is a Greek letter and thus an identifier as good as any other, although you will have a hard time finding that letter on an English keyboard. Fortunately, most operating systems nowadays provide you with an applet that lets you enter foreign language characters and other special symbols with ease.

1.5.4 Defining Functions

Now that we’ve learned how to run the interpreter and evaluate some expressions, it’s time to embark on some real programming. Like in other functional programming languages, we do this by defining functions which perform the desired computation. The form these definitions take in Pure is a collection of rewriting rules which specify how an application of the function reduces to another expression which then gets evaluated recursively to give the value of the function application.

In the simplest case, the left-hand side of a rewriting rule may just specify the function name along with some argument names. For instance:

square x = x*x;

Now, if we evaluate an expression like square 7, it reduces to 7*7 which in turn reduces to 49 by the built-in rules for integer arithmetic. You can verify this by entering the definition.
in the interpreter:
> square x = x*x;
> square 7;
49

In fact, the above definition is completely generic; since \( x \) is an unqualified variable, we can apply square to *any* value \( x \) and have it evaluate to \( x \times x \):

> square 7.0;
49.0
> square 7L;
49L
> square (a+b);
(a+b)*(a+b)

As the last example shows, this will even work if the supplied argument is no number at all, which is useful, e.g., if we want to do symbolic evaluations.

Functions can have as many arguments as you like, subject to the constraint that each equation defining the function has the *same* number of arguments on the left-hand side. For instance, suppose that we want to calculate the sum of two squares. We can do this using the square function from above as follows:

> sumsquares x y = square x + square y;
> sumsquares 3 4;
25

The interpreter keeps track of the number of arguments of each defined function, so if we accidentally try to define sumsquares with three arguments later then we’ll get an error message:

> sumsquares x y z = square x + square y + square z;
<stdin>, line 8: function 'sumsquares' was previously defined with 2 args

This actually makes perfect sense if you think about the way curried function applications work. If the above was permitted, then an expression like sumsquares \( x \ y \) would become ambiguous (would it denote an invocation of the binary sumsquares or a partial application of the ternary one?).

Thus Pure doesn’t really have *variadic* functions which take a variable number of arguments. There are ways to emulate this behaviour in some cases, but usually it’s easier to just pass the arguments as a single structured value instead. It is customary to employ tuples for this purpose, so that the call uses the familiar notation \( f (x, y, z) \). A typical example are optional arguments. For instance, suppose that we’d like to define a function incr which increments a numeric value, where the amount to be added can be specified as an optional second value which defaults to 1. This can be done in Pure as follows:

\[
\text{incr } (x,y) = x+y;
\text{incr } x = x+1 \text{ otherwise};
\]

These equations *must* be in the indicated order. Pure considers different equations for the same function in the order in which they are written. Therefore “special case” rules, like the
one for \( \text{incr} (x,y) \) in this example, must be listed first. (Note that if the second equation came first, \( \text{incr} (5,2) \) would reduce to \( (5,2)+1 \) rather than \( 5+2 \), because \( x \) also matches, in particular, any tuple \( x,y \).)

Functions taking a single tuple argument are also (somewhat misleadingly) called **uncurried** functions, because their arguments have to be given all in one go, which precludes partial applications of the function. While curried functions are often preferred, uncurried functions can be more convenient at times, e.g., if you have to map a function to a list containing given combinations of arguments. For instance, given the above definition of \( \text{incr} \) we may write:

\[
\text{map } \text{incr} \ [(5,1),(5,2),(6,3),(7,5)]; \\
[6,7,9,12]
\]

To make this work with curried functions, the prelude provides a function \( \text{uncurry} \) which turns a curried function of two arguments into an uncurried one which takes a single tuple argument:

\[
\text{map } (\text{uncurry } (+)) \ [(5,1),(5,2),(6,3),(7,5)]; \\
[6,7,9,12]
\]

On the other hand, some generic list processing functions such as \( \text{foldl} \) expect curried functions, so the reverse transformation \( \text{curry} \) is also provided:

\[
\text{foldl } (\text{curry } \text{incr}) \ 0 \ (1..10); \\
55
\]

In fact, the definitions of \( \text{curry} \) and \( \text{uncurry} \) don’t involve any special magic, they just translate curried calls to uncurried ones and vice versa. From the horse’s mouth:

\[
\text{show curry uncurry} \\
\text{curry } f \ x \ y = f \ (x,y); \\
\text{uncurry } f \ (x,y) = f \ x \ y;
\]

A function can also have zero arguments, i.e., you can define parameterless functions such as:

\[
\text{foo} = 1..3;
\]

The function is then simply invoked without any arguments:

\[
\text{foo}; \\
[1,2,3]
\]

It is worth noting the difference between this and the variable definition:

\[
\text{let } \text{bar} = 1..3;
\]

While \( \text{bar} \) and \( \text{foo} \) yield the same result \([1,2,3]\), they do so in different ways. \( \text{bar} \) is a global variable whose value is computed once and then stored under its name, so that the value can be simply recalled when \( \text{bar} \) is later invoked in an expression. Also, the value of \( \text{bar} \) can be changed at any time with an appropriate \( \text{let} \) statement. (If the value is not supposed to change later then you can also define it as a \( \text{const} \) instead.)
In contrast, `foo` is a function which recomputes the list value on each invocation. To avoid the overhead of recalculating the same value each time it is needed, a variable or constant is usually preferred over a parameterless function in Pure. However, a parameterless function will be needed if the computation involves some hidden side effects which cause a new value to be produced for each invocation. For instance, the `math` module provides a parameterless function `random` which computes a new pseudo random number each time it is called:

```plaintext
> using math;
> random, random, random;
-795755684,581869302,-404620562
```

Many functions also involve conditionals which let them take different computation paths depending on the outcome of a condition. One way to do this is to employ a **conditional expression**. For instance, we may compute the sign of a number as follows:

```plaintext
> sign x = if x>0 then 1 else if x<0 then -1 else 0;
> map sign (-3..3);
[-1,-1,-1,0,1,1,1]
```

Alternatively, you can also use a collection of **conditional rules** instead:

```plaintext
sign x = 1 if x>0;
    = -1 if x<0;
    = 0 otherwise;
```

Note that here we omitted the left-hand side in the second and third equations, in which case the compiler assumes that it’s the same as for the first equation; cf. [Rule Syntax](#) for details. Also note that the `otherwise` keyword is only syntactic sugar in Pure, you can always omit it. However, it tends to improve readability by marking the default case of a definition.

Both styles are frequently used in Pure programs; it depends on the situation which one is more appropriate. Conditional rules make the conditions stick out more clearly and hence tend to improve readability. On the other hand, conditional expressions can be nested more easily and thus facilitate the programming of complicated decision trees.

Function definitions may also be recursive, i.e., a function may invoke itself either directly or indirectly in its definition. For instance, here is a definition of the Ackerman function using conditional rules:

```plaintext
ack x y = y+1 if x == 0;
    = ack (x-1) 1 if y == 0;
    = ack (x-1) (ack x (y-1)) otherwise;
```

We will have more to say about recursive functions later; see [Recursion](#) below.

### 1.5.5 Pattern Matching

So far we have only seen function definitions involving just unqualified variables as parameters. In general it is possible to specify arbitrary **patterns** for the parameters, in which case the actual arguments are checked against the patterns and, if everything matches up,
the right-hand side of the rule is invoked with the variables in the patterns bound to their corresponding values.

The simplest nontrivial patterns are type tags which can be placed on a variable to restrict the type of value an argument can match. For instance:

```plaintext
> square x::int = x*x;
> square 7;
49
```

Note that in contrast to our previous generic definition of the `square` function we gave in Defining Functions, this definition now only applies to the case of an `int` argument:

```plaintext
> square 7.0;
square 7.0
```

Polymorphic definitions can be made by giving separate equations for the different argument types. For instance, we can easily add an equation for the `double` case:

```plaintext
> square x::double = x*x;
> show square
square x::int = x*x;
square x::double = x*x;
> square 7; square 7.0;
49
49.0
```

Here the right-hand sides of both rules are the same. Pure has a convenient shorthand notation for this case which lets you factor out the common right-hand side using the `|` delimiter as follows:

```plaintext
square x::int | square x::double = x*x;
```

The compiler expands this to the same two rules as above:

```plaintext
square x::int = x*x;
square x::double = x*x;
```

Let’s compare this to our earlier generic definition of `square`:

```plaintext
square x = x*x;
```

There are two different kinds of polymorphism at work here. The latter, generic definition is an example of parametric polymorphism; it applies to any type of argument `x` whatsoever (at least if it makes sense to multiply a member of the type with itself). Also note that this definition is “closed”; because equations are considered in the order in which they are written, there’s no way you could add another “special case” rule to this definition later.

In contrast, the former definition leaves any application of `square` to a value other than `int` or `double` undefined. This gives us the opportunity to define `square` on as many types of arguments as we like, and (this is the crucial point) define the function in different ways for different argument types. This is also known as ad-hoc polymorphism or function overloading. For instance, if we later need to square 2x2 matrices, we might add a rule like:

```
```

1.5.5 Pattern Matching
square \{a,b;c,d\} = \{a*a+b*c,a*b+b*d;c*a+d*c,c*b+d*d\};

Pure places no restriction on the number of equations used to define a function, and the different equations may in fact be scattered out over many different places. So as long as the left-hand side patterns properly discriminate between the different cases, you can overload any operation in Pure to handle as many argument types as you want. However, it is important to note that in contrast to overloaded functions in statically typed languages such as C++, there’s really only one square function here which handles all the different argument types. The necessary “dispatching” to select the proper rewriting rule for the argument values at hand is done at runtime by pattern matching.

Parametric polymorphism has the advantage that it lets you define polymorphic functions in a very concise way. On the other hand, ad-hoc polymorphism lets you deal with disparate cases of an operation which cannot easily be reconciled. It also allows you to tailor the definition to the specific case at hand, which might be more efficient than using a generic rule. You can also combine both approaches, but in this case you have to list the special case rules before the generic ones. For instance:

```plaintext
square x::int | square x::double |
square x = x*x;
```

(Note that the first two rules are just specialization of the last rule to int and double arguments, so we could in fact eliminate the special case rules here and still get the same results. But the type tags tell the compiler that the argument in these rules is always an int or double, respectively, so it may generate more efficient code for these cases.)

Patterns may also involve constant values, in which case the constant must be matched literally in the argument. For instance, here is another definition of the Ackerman function from Defining Functions which uses constant argument patterns instead of conditional rules:

```plaintext
ack 0 y = y+1;
ack x 0 = ack (x-1) 1;
ack x y = ack (x-1) (ack x (y-1)) otherwise;
```

The first two rules take care of the “base cases” \( x=0 \) and \( y=0 \). Note that these rules must be given in the indicated order to make them work. Specifically, the left-hand side \( \text{ack } x \ y \) of the last equation also matches, in particular, terms like \( \text{ack } 0 \ y \) and \( \text{ack } x \ 0 \), so placing the last equation before the first two will “shadow” those rules and cause non-termination, resulting in a stack overflow. Similarly, placing the second equation before the first one will cause the definition to loop on \( \text{ack } 0 \ 0 \).

Another point that deserves mentioning here is that constants on the left-hand side of a rule must be matched literally, cf. Constant Patterns. E.g., \( \text{ack } 0 \ y \) only matches if the first argument is really 0, not 0.0 or 0L (although these compare equal to 0). So the above definition of ack isn’t quite the same as our previous definition from Defining Functions. If you wanted the definition above to also work with double and bigint values, you’d have to add corresponding rules for the 0.0 and 0L cases.

Last but not least, patterns are also used to “deconstruct” structured values like lists, tuples and matrices, binding variables to the component values. For instance, to compute the sum
of a list of values, you may write:

```haskell
> sum [] = 0;
> sum (x:xs) = x+sum xs;
> sum (1..100);
5050
```

This definition works in a straightforward recursive manner. The first rule involves the
constant pattern `[]` and thus handles the base case of an empty list, in which case the sum
is zero. The second rule has a structured argument pattern `x:xs` which denotes a list with
head element `x` and tail `xs`; in this case the result is `x` added to the sum of the remaining list
elements `xs`. (In fact, this computational pattern is so common that the prelude provides a
family of functions such as `foldl` and `foldr` to do this kind of operation in a generic way.
Our `sum` function above is actually equivalent to `foldr (+) 0`, see List Processing below for
details.)

Instead of placing the patterns directly into the left-hand sides of the function definition, you
might also do the necessary pattern-matching in the right hand side, by employing a `case`
expression:

```haskell
sum xs = case xs of [] = 0; x:xs = x+sum xs end;
```

This works a bit different, though, since a `case` expression raises an exception if the target
expression is not matched (cf. Patterns):

```haskell
> sum (1:2:xs);
<stdin>, line 2: unhandled exception ‘failed_match’ while evaluating ‘sum (1:2:xs)’
```

To avoid that, you may want to add a type tag, which ensures that the argument of `sum` is of
the proper type:

```haskell
sum xs::list = case xs of [] = 0; x:xs = x+sum xs end;
```

Now the case of an improper list is handled a bit more gracefully, yielding the same normal
form expression you’d get with the first definition of `sum` above:

```haskell
> sum (1:2:xs);
1+(2+sum xs)
```

Pure also allows to define `sum` in a more traditional way which will be familiar to Lisp pro-
grammers (note that `head` and `tail` correspond to Lisp’s “car” and “cdr”):

```haskell
sum xs::list = if null xs then 0 else head xs + sum (tail xs);
```

Choosing one or the other is again a question of style. However, if you’re dealing with
concrete data structures such as lists, pattern-matching definitions are often more convenient
and easier to understand.

Pattern matching also works with user-defined constructors (cf. Data Types). For instance,
here’s how to implement an insertion operation which can be used to construct a binary tree
data structure useful for sorting and searching:
nonfix nil;

insert nil y = bin y nil nil;
insert (bin x L R) y = bin x (insert L y) R if y<x;
= bin x L (insert R y) otherwise;

Note that nil needs to be declared as a nonfix symbol here, so that the compiler doesn’t mistake it for a variable; see The “Head = Function” Rule for details. The following example illustrates how the above definition may be used to obtain a binary tree data structure from a list:

> tree [] = nil;
> tree (x:xs) = insert (tree xs) x;
> tree [7,12,9,5];
bin 5 nil (bin 9 (bin 7 nil nil) (bin 12 nil nil))

Conversely, it’s also easy to convert such a tree structure back to a list. We can then combine these operations to sort a list in ascending order:

> list nil = [];
> list (bin x L R) = list L + (x:list R);
> list (tree [7,12,9,5]);
[5,7,9,12]

1.5.6 Local Functions and Variables

Up to this point our examples only involved global functions and variables. When the problems to be solved become more difficult, it will be necessary to structure the solution in some way, so that you’ll often end up with many small functions which need to work in concert to solve the problem at hand. Typically only a few of these functions will serve as actual entry points, while other functions are only to be used internally. Pure supports this through local functions and variables whose scope is limited either to the right-hand side of a rule or one of its subexpression. This offers two main advantages:

- Local functions and variables are hidden from the main scope so that they can only be used in the context where they are needed and don’t clutter up the global environment. This provides a way to define functions in a modular fashion while hiding internal details from the rest of the program.

- The right-hand sides of local definitions have full access to other local functions and variables in their parent environments, which eliminates the “plumbing” which would otherwise be needed to pass these values around. For instance, a local function nested in another function can freely access the parent function’s arguments and other local variables in its scope.

Local functions are defined using the with construct, while local variables can be introduced with a when or case expression, see Special Expressions for details. These constructs can be tacked on to any expression, and they can also be nested. For instance:
> f 5 with f x = y+y when y = x*x end end;
50

Note that the local function \( f \) there computes twice the square of its argument \( x \). To these ends, first \( x \times x \) is assigned to the local variable \( y \) whose value is then doubled by computing \( y + y \) which becomes the result of \( f \).

Local functions can also be created without actually naming them, by employing a so-called lambda abstraction. For instance, a function which squares its argument might be denoted as \( \lambda x \rightarrow x \times x \). This is pretty much the same as a local function \( f \) with \( f \ x = x \times x \) end except that the function remains nameless. This notation is pretty convenient for making up little “one-off” functions which are to be applied on the spot or passed as function arguments or results to other functions. For instance, here’s how you can compute the first ten squares, first with an ordinary (named) local function, and then with an equivalent lambda:

\[
\text{map } f \ (1..10) \ 
\text{with } f \ x = x \times x \text{ end end;}
\]

\[ [1, 4, 9, 16, 25, 36, 49, 64, 81, 100] \]

\[
\text{map } \ (\lambda x \rightarrow x \times x) \ (1..10);\]

\[ [1, 4, 9, 16, 25, 36, 49, 64, 81, 100] \]

For obvious reasons lambdas work best for non-recursive functions. While there are techniques to create recursive functions out of lambdas using so-called fixed point combinators (cf. \texttt{fix}), named functions are much more convenient for that purpose.

Pattern matching works in local definitions as usual. For instance, here are several ways to swap two values represented as a tuple, using either a local function or a \texttt{when} or \texttt{case} expression:

\[
\text{swap } (1, 2) \ 
\text{with } \text{swap} \ (x,y) = y,x \text{ end end;}
\]

\[ 2, 1 \]

\[
(\lambda (x,y) \rightarrow y,x) \ (1,2);
\]

\[ 2, 1 \]

\[
\text{y,x when } x,y = 1,2 \text{ end end;}
\]

\[ 2, 1 \]

\[
\text{case } 1,2 \ 
\text{of } x,y = y,x \text{ end end;}
\]

\[ 2, 1 \]

You’ll also frequently find code like the following, where a global “wrapper” function just sets up some initial parameter values and then invokes a local “worker” function which does all the real work. The following function calculates the sum of the positive integers up to \( n \) (the “accumulating parameters” technique used in this example will be explained later, cf. \texttt{Recursion}).

\[
\text{sum } n = \text{sum } 0 \ n \ 
\text{with }
\begin{align*}
\text{sum } s \ n & = s \ 
\text{if } n < 0; \\
& = \text{sum } (s+n) \ (n-1) \ 
\text{otherwise;}
\end{align*}
\text{end;}
\]

Note that there are actually two separate functions named \texttt{sum} here. This works because according to the \texttt{scoping rules} the right-hand side of the global definition is under the scope of the \texttt{with} clause, and thus the call \texttt{sum 0 n} on the right-hand refers to the local \texttt{sum} function,
not the global one. (While it is perfectly correct and even makes sense in this example, this style may be somewhat confusing, so we often prefer to give wrapper and worker different names for clarity.)

As discussed in Scoping Rules, a local function can refer to other local functions and variables in its parent environments. It can also be returned as a function value, which is where things get really interesting. The local function value then becomes a **lexical closure** which carries around with it the local variable environment it was created in. For instance:

```plaintext
adder x = add with y = x+y end;
let g = adder 5; g; map g (1..5);
add [6,7,8,9,10]
```

Note that here the local function `add` refers to the argument value `x` of its parent function `adder`. The invocation `adder 5` thus returns an instance of `add` which has `x` bound to the value `5`, so that `add y` reduces to `5+y` for each `y`. This works as if this instance of the add closure had an invisible `x` argument of `5` attached to it. (And this is in fact how closures are implemented internally, using a transformation called lambda lifting which effectively turns local functions into global ones.) You should study this example carefully until you fully understand how it works; we’ll see a bunch of other, more complicated examples of this kind later.

Lexical closures also provide a means to encapsulate data in a way reminiscent of object-oriented programming. For instance:

```plaintext
nonfix coords;
point (x,y) = \msg -> case msg of
  coords = x,y;
  move (dx,dy) = point (x+dx,y+dy);
end;
```

The anonymous function returned by `point` in fact works like an “object” which can be queried for its coordinates and moved by a given offset through corresponding “messages” passed as arguments to the object:

```plaintext
> let p = point (1,2); p;
#<closure 0x7f420660e658>
> p coords; p (move (2,3)) coords;
1,2
3,5
```

Note that this still lacks some typical features of object-oriented programming such as mutability and inheritance. It isn’t really hard to add these, but this requires the use of some of Pure’s more advanced machinery which we didn’t discuss yet. For instance, mutability can be implemented in Pure by using so-called expression references, a kind of mutable storage cells which can hold arbitrary expression values:

```plaintext
> let x = ref 99; get x;
99
```
Using these we can rewrite our definition of the point object as follows:

```plaintext
nonfix coords;

point (x,y) = (msg -> case msg of
  coords = get x, get y;
  move (dx,dy) = put x (get x+dx), put y (get y+dy);
end) when
  x,y = ref x,ref y;
end;
```

Note that the coordinates are kept in corresponding expression references assigned to the local x and y variables, which now shadow the x and y arguments of point. This makes it possible to have move actually modify the point object in-place:

```plaintext
> let p = point (1,2); p coords;
1,2
> p (move (2,3)); p coords;
3,5
3,5
```

It goes without saying that this style isn’t preferred in functional programs, but it certainly has its uses, especially when interfacing to imperative code written in other languages such as C.

### 1.5.7 Data Types

Before we consider the more advanced uses of functions in Pure, a few remarks about data types are in order. Like Lisp, Pure is basically a “typeless” language. That doesn’t mean that there are no data types; in fact, they’re a dime a dozen in Pure. But Pure lets you make up your own data structures as you go, without even formally defining a data type. Data types can be defined and associated with a name pretty much in the same way as functions, but that’s just a convenience and completely optional. This sets Pure apart from statically typed languages like ML and Haskell, where explicit data type definitions are mandatory if you want to introduce new data structures.

As we’ve seen, Pure knows about a few built-in types such as numbers, strings, symbols and functions; everything else is a function application. If a symbol is defined as a function, which merely means that there are some rewriting rules for it, then an application of that function to some arguments may evaluate to something else. But if it doesn’t, then Pure is perfectly happy with that; it just means that the function application is in normal form and thus becomes a “value”. For instance:

```plaintext
> cons 3 (cons 5 nil);
cons 3 (cons 5 nil)
```
There’s nothing mysterious about this; the cons and nil symbols being used here aren’t defined anywhere, and thus any terms constructed with these symbols are just “data”, no questions asked. We also call such symbols constructors. (Note that these are different from constructors in object-oriented programming; constructor applications in term rewriting and functional programming normally don’t execute any code, they’re just literal data objects.)

We can now go ahead and define some operations on this kind of data. (To these ends, it’s necessary to declare nil as a nonfix symbol so that we can use it as a literal in patterns; cf. Pattern Matching.)

\[
\text{nonfix nil;}
\]

\[
\#\text{nil} = 0;
\]

\[
\#\text{cons } x \text{ xs} = \#\text{xs} + 1;
\]

\[
\text{head } (\text{cons } x \text{ xs}) = x;
\]

\[
\text{tail } (\text{cons } x \text{ xs}) = \text{xs};
\]

\[
\text{nil} + \text{ys} = \text{ys};
\]

\[
\text{cons } x \text{ xs} + \text{ys} = \text{cons } x \text{ (xs + ys)};
\]

Et voilà, we’ve just created our own list data structure! It’s admittedly still a bit paltry, but if we keep at it and define all the other functions that we need then we could turn it into a full-blown replacement for Pure’s list data structure. In fact Pure’s lists work in a very similar fashion, using the infix ‘:’ constructor and the empty list [] in lieu of cons and nil, respectively.

If we want, we can define a new data type for the data structure we just invented. This works by giving a number of type rules similar to those used in function definitions. In general, these may denote arbitrary unary predicates, but in our case it’s sufficient to just list the patterns of terms which are supposed to be members of the type (see Type Rules for an explanation of the definition syntax):

\[
\text{type mylist nil | mylist } (\text{cons } x \text{ xs});
\]

This definition lets us use the mylist type as a tag on the left-hand side of an equation, cf. Pattern Matching. But if we’re content with using the patterns directly then we might just as well do without that.

Types consisting solely of constructor term patterns are sometimes also called algebraic types. In fact, most user-defined data structures are algebraic types in Pure, and there are plenty of examples of these in the standard library as well. In particular, lists and tuples are algebraic types, as are complex and rational numbers, and most of Pure’s container data types such as dictionaries and sets are also implemented as algebraic types.

Pure differs from most functional languages in that symbols may act as both constructors and defined functions, depending on the arguments. Thus Pure allows you to have “constructors with equations”. For instance:

\[
\text{cons nil ys} = \text{ys};
\]

\[
\text{cons } (\text{cons } x \text{ xs}) \text{ ys} = \text{cons } x \text{ (cons } x \text{ xs } \text{ ys)};
\]
Now \texttt{cons} has become a (partially) defined function. Note that these rules make \texttt{cons} associative and turn \texttt{nil} into a left-neutral element for \texttt{cons}. This in fact makes \texttt{cons} behave like concatenation, so that our lists are always flat now:

\begin{verbatim}
> cons (cons 1 (cons 2 nil)) (cons 3 nil);
cons 1 (cons 2 (cons 3 nil))
\end{verbatim}

Examples of such constructor equations can be found in the standard library as well, such as the rules used to flatten tuples, keep rational numbers in lowest terms, or confine the angles of complex numbers in polar notation.

Another possible use of constructor equations is to check the well-formedness of constructor terms. For instance, in our example we might want to preclude terms like \texttt{cons 1 2} which don’t have a \texttt{mylist} in the second argument to \texttt{cons}. This can be done with a constructor equation which raises an exception in such cases (cf. Exception Handling):

\begin{verbatim}
> cons x y = throw (bad_mylist y) if ~typep mylist y;
> cons 1 2;
<stdin>, line 18: unhandled exception ‘bad_mylist 2’ while evaluating ‘cons 1 2’
\end{verbatim}

A specific kind of algebraic data types which are useful in many applications are the enumerated types. In this case the type consists of symbolic constants (nonfix symbols) only, which are the elements of the type. For instance:

\begin{verbatim}
nonfix sun mon tue wed thu fri sat;
type day sun | day mon | day tue | day wed | day thu | day fri | day sat;
\end{verbatim}

However, to make this type actually work as an enumerated type, we may want to provide definitions for basic arithmetic, \texttt{ord}, \texttt{succ}, etc. This is rather straightforward, but tedious. So as of Pure 0.56, the standard library provides a little utility module, \texttt{enum}, which generates the necessary definitions in an automatic fashion. All we have to do is to import the module and then invoke the \texttt{enum} function on the type and we’re set:

\begin{verbatim}
using enum;
enum day;
\end{verbatim}

It’s also possible to define the type and make it enumerable in one go using the \texttt{defenum} function:

\begin{verbatim}
defenum day [sun,mon,tue,wed,thu,fri,sat];
\end{verbatim}

In either case, we can now perform calculations with the members of the type just like with other predefined enumerated types such as numbers and characters:

\begin{verbatim}
> ord sun;
0
> day (ans+3);
wed
> pred sat;
Fri
> sun+3;
Wed
\end{verbatim}
A more abstract way to define algebraic types are the interface types. For instance, if we take another look at the operations defined on our list type, we may observe that the data structure is quite apparent from the patterns in the rules of operations such as `#` and `+`. Pure lets us leverage that information by creating an algebraic type from a collection of operation patterns it supports. For instance, we may write:

```
interface list_alike
  #x::list_alike;
  x::list_alike + y;
end;
```

This defines a generic type consisting of all terms which may be passed as an argument to both `#` and `+`. We can ask the interpreter about the patterns actually matched by the type as follows:

```
> show interface list_alike
type list_alike s::string;
type list_alike [];
type list_alike (x:xs);
type list_alike nil;
type list_alike (cons x xs);
```

Note that the `list_alike` type not only includes our own list type, but also any other data structure providing the `#` and `+` operations. This also comprises the standard list and string types for which there are definitions of the `#` and `+` operations in the prelude.

Pure’s interface types are a first attempt at formalizing the notion of Duck typing in Pure. They are thus still a bit experimental and require some diligence in defining the interface operations in a suitable way. Please check Interface Types in the Declarations section for more information and examples.

### 1.5.8 Recursion

Recursion means that a function calls itself, either directly or indirectly. It is one of the most fundamental techniques in functional programming, and you won’t find many useful Pure programs which don’t use it in one form or another. That’s because most interesting programs execute pieces of code repeatedly. Pure doesn’t have any special looping constructs, so recursion is the only way to do this in Pure. We’ve already seen various examples of this throughout the manual, so let’s take a closer look at it now and learn a few related tricks along the way.
For a simple example, consider the factorial. In order to compute the factorial of an integer \( n \), we need to multiply the positive integers up to \( n \). There’s a straightforward recursive definition which does this:

```haskell
fact n = if n>0 then n*fact (n-1) else 1;
```

If you prefer conditional rules instead, you can also write:

```haskell
fact n = n*fact (n-1) if n>0;
    = 1 otherwise;
```

It’s not hard to see how this definition operates. The first rule only applies if \( n>0 \), otherwise the second rule kicks in so that \( \text{fact } n \) becomes 1 if \( n \) is zero or negative (which is consistent with our informal description because in this case the product of all positive integers up to \( n \) is the empty product which is 1 by mathematical convention). The first rule is the interesting one where the recursion happens. If \( n>0 \) then we may compute \( \text{fact } n \) by computing \( \text{fact } (n-1) \) recursively and multiplying that with \( n \), giving \( n*(n-1)*\ldots*1 \). Let’s check that this works:

```haskell
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

Note that these numbers grow fairly quickly; they outgrow the 32 bit range and start wrapping around already at \( n==13 \). To avoid that, you’ll have to do the computation with bigints, or you could use floating point values if you don’t mind the limited precision.

```haskell
> fact 13;
1932053504
> fact 13L;
6227020800
> fact 30L;
26525285981219105863630848000000000L
> fact 30.0;
2.65252859812191e+32
```

However, you’ll run into another, more serious obstacle if you want to compute factorials for some really big values of \( n \). For instance:

```haskell
> fact 200000L;
<stdin>, line 7: unhandled exception ‘stack_fault’ while evaluating ‘fact 200000L’
```

Oops. What happened there? Well, each recursive invocation of \( \text{fact} \) needs some small amount of memory on the execution stack, a so-called “stack frame”. Thus, when \( n \) becomes big enough then our definition is in danger of running out of stack space. (This is also why you keep hearing in most CS 101 courses that you should try to avoid recursion. If you’ve forgotten how subroutine calls are executed by keeping the execution context on a stack then it’s time to revisit those CS 101 lecture notes now.)

So how can we avoid using all that stack space? In a language like C we’d be using a specialized loop construct instead of recursion, e.g.
int fact(int n)
{
    int p = 1;
    while (n>0) { p = n*p; n = n-1; }
    return p;
}

Pure doesn’t have a while loop, but we can rewrite the definition so that it becomes tail-recursive. This means that the recursive call becomes the final operation on the right-hand side of the recursive rule. The Pure compiler treats this pretty much like a loop in traditional programming languages.

The trick of the trade to turn a recursive function into a tail-recursive one is the accumulating parameter technique. The idea here is to have a separate “worker” function which carries around an extra argument representing the intermediate result for the current iteration. The final value of that parameter is then returned as the result. In the case of the factorial this can be done as follows:

```plaintext
fact n = loop n 1 with
    loop n p = loop (n-1) (n*p) if n>0;
        = p otherwise;
end;
```

Note that fact has now become a simple “wrapper” which supplies the initial value of the accumulating parameter (p in this case) for the “worker” function loop which does all the hard work. This kind of design is fairly common in functional programs.

Our worker function is tail-recursive since the recursive call to loop is indeed the final call on the right-hand side of the first equation defining loop. The Pure compiler generates code which optimizes such “tail calls” so that they reuse the stack frame of the calling function. Thus a tail-recursive function like loop will execute in constant stack space; in fact it will be just as efficient as the while loop in our little C snippet above (up to constant factors, of course). After entering our new definition of fact we can now compute fact 200000L just fine (this may take a little while, though, depending on how fast your computer is; the result has 973351 digits):

```plaintext
> fact 200000L:
1420225345470314404966946336823059760899... // lots of digits follow
```

The accumulating parameter technique isn’t fully general, but it covers all the kinds of simple iterative algorithms which you’d do using loop constructs in traditional programming languages. Some algorithms may require additional techniques such as tabulation (keeping track of some or all intermediate results), however, so that they can be written in an iterative form. To see how this can be done in Pure, let’s consider the Fibonacci numbers. These can be computed with the following naïve recursive definition:

```plaintext
fib n = if n<=1 then n else fib (n-2) + fib (n-1);
```

Here are some members of this famous sequence:
> map fib [0..20];
[0,1,1,2,3,5,8,13,21,34,55,89,144,233,377,610,987,1597,2584,4181,6765]

Note that the right-hand side of the definition above involves *two* recursive invocations of the `fib` function in the `else` branch. This is bad because it means our definition will need exponential running time. (More precisely, you'll find that the ratio between the running times of successive invocations quickly starts approaching the golden ratio \( \phi = 1.618... \), which is no accident because the times are proportional to the Fibonacci function itself!)

Using a simple iterative algorithm, it is possible to calculate the Fibonacci numbers in linear time instead. Observe that each member of the sequence is simply the sum of the two preceding members. If we keep track of the last two members of the sequence then we can compute the next member with a single addition. This yields the following tail-recursive implementation which uses the same kind of “wrapper-worker” design:

```plaintext
fib n = loop n 0L 1L with
  loop n a b = loop (n-1) b (a+b) if n>0;
  = a otherwise;
end;
```

Note that as a matter of prudence we primed the iteration with the bigints `0L` and `1L` so that we can compute large Fibonacci numbers without suffering wrap-around. For instance, try the following:

> fib 1000000;
1953282128707757731632014947596256332443... // lots of digits follow

Recursion also naturally occurs when traversing recursive data structures. We've already seen various examples of these, such as the binary tree data structure:

```plaintext
nonfix nil;

insert nil y = bin y nil nil;
insert (bin x L R) y = bin x (insert L y) R if y<x;
          = bin x L (insert R y) otherwise;
```

The `insert` function implements a binary tree insertion algorithm which keeps the tree (represented with the `bin` and `nil` constructor symbols) sorted. To these ends, it recurses into the left or right subtree, depending on whether the element `y` to be inserted is less than the current element `x` or not. The final result is a new tree which has a `nil` subtree replaced with a new `bin y nil nil` subtree at the right location.

If we do an `inorder` traversal of such a binary tree (at each non-nil subtree, first visit the left subtree, then note the element at the top of the current subtree, and finally visit the right subtree), we obtain the elements of the tree in ascending order. This traversal is also implemented recursively, e.g., as follows:

```plaintext
list nil = [];
list (bin x L R) = list L + (x:list R);
```

Note that these functions can't be made tail-recursive using the accumulating parameter
technique, because traversing a tree structure requires more general forms of recursion. There is in fact a more general continuation passing technique to do this, which we will look at in The Same-Fringe Problem below; alas, it’s not as easy as accumulating parameters. Fortunately, some important recursive structures such as lists only involve simple recursion and can thus be traversed and manipulated in a tail-recursive fashion more easily. For instance, consider our earlier definition of the sum function:

\[
\text{sum}~[] = 0; \\
\text{sum}~(x:xs) = x + \text{sum}~xs;
\]

This definition isn’t tail-recursive, but we can easily massage it into this form using the accumulating parameter technique:

\[
\text{sum}~xs::\text{list} = \text{loop}~0~xs~\text{with} \\
\text{loop}~s~[] = s; \\
\text{loop}~s~(x:xs) = \text{loop}~(s + x)~xs;
\]

Functions can also be mutually recursive, in which case two or more functions are defined in terms of each other. For instance, suppose that we’d like to skip every other element of a list (i.e., return a list with only the elements having either even or odd indices, respectively). One way to do this involves two functions (named \text{pick} and \text{skip} here) which recursively call each other:

\[
> \text{pick}~[] = []; \quad \text{pick}~(x:xs) = x:\text{skip}~xs; \\
> \text{skip}~[] = []; \quad \text{skip}~(x:xs) = \text{pick}~xs; \\
> \text{pick}~(1..10); \quad [1,3,5,7,9] \\
> \text{skip}~(1..10); \quad [2,4,6,8,10]
\]

A Numeric Root Finder

Let’s now see how we can apply the techniques explained above in the context of a somewhat more practical example: a numeric root finder. That is, we’re going to write a function which takes another function \( f \) and determines a (double) value \( x \) such that \( f(x) \) becomes (close to) zero.

We’ll develop this in a bottom-up fashion. The method we employ here is known as the Newton-Raphson algorithm, whose basic building block is the following routine \text{improve} which improves a given candidate solution \( x \) by computing a first-order approximation of the root. This involves computing (a numeric approximation of) the first derivative at the given point, which we do using a second function \text{derive}:

\[
\text{improve}~f~x = x - f(x) / \text{derive}~f~x; \\
\text{derive}~f~x = (f(x+dx) - f(x)) / dx;
\]

If you still remember your calculus then these should look familiar. Note that in both functions, \( f \) is our target function to be solved and \( x \) the current candidate solution. The second equation is nothing but the difference quotient of the function at the point \( x \), using \( dx \) as
the increment along the x axis. The improve function computes the intersection of the corresponding secant of f with the x axis.

To illustrate how the method works, let’s perform a few improvement steps manually, using the target function \( f(x) = x^2 - 2 \) which becomes zero at the square root of 2. Here we choose a \( dx \) value of \( 1e-8 \) and start from the initial guess 2:

```plaintext
> let dx = 1e-8;
> improve f x = x - f x / derive f x;
> derive f x = (f (x+dx) - f x) / dx;
> f x = x^2 - 2;
> improve f 2;
> improve f ans;
> improve f ans;
> improve f ans;
```

It should be apparent by now that this converges to the square root of 2 rather quickly. To automate this process, we need another little helper function which iterates improve until the current candidate solution is “good enough”. A suitable termination criterion is that the improvement drops below a certain threshold (i.e., \( \text{abs}(x-f(x)) \leq dy \) for some reasonably small \( dy \)). For extra safety, we’ll also bail out of the loop if a prescribed number \( n \) of iterations has been performed. This function can be implemented in a tail-recursive fashion as follows:

```plaintext
loop n f x = x if n <= 0;
    = if abs(x-y) < dy then y else loop (n-1) f y when y = f x end;
```

Let’s give it a try:

```plaintext
> let dy = 1e-12;
> loop n f x = x if n <= 0;
>    = if abs(x-y) < dy then y else loop (n-1) f y when y = f x end;
> loop 20 (improve dx f) 2;
> ans*ans;
```

Looks good. So let’s finally wrap this up in a main entry point solve which takes the function to be solved and an initial guess as parameters. Our little helper functions improve, derive and loop are only used internally, so we can turn them into local functions of solve. The additional parameters of the algorithm are implemented as global variables so that we can easily modify their values if needed. The end result looks as follows. Note that the initial guess \( x \) is an implicit parameter of the solve function, so the function actually gets invoked as solve \( f(x) \).

```plaintext
let dx = 1e-8; // delta value for the approximation of the derivative
let dy = 1e-12; // delta value for testing convergence
let nmax = 20; // maximum number of iterations
```
```haskell
solve f = loop nmax (improve f) with
  loop n f x = x if n <= 0;
  = if abs (x-y) < dy then y else loop (n-1) f y when y = f x end;
  improve f x = x - f x / derive f x;
  derive f x = (f (x+dx) - f x) / dx;
end;
```

Here are some examples showing how the `solve` function is used. Note that we specify the target functions to be solved as lambdas here. E.g., `\t -> t^3-x` denotes a function mapping `t` to `t^3-x`, which becomes zero if `t` equals the cube root of `x`.

```haskell
> sqrt x = solve (\t -> t*t-x) x;
> sqrt 2; sqrt 5;
1.4142135623731
2.23606797749979

> cubrt x = solve (\t -> t^3-x) x;
> cubrt 8;
2.0
```

Our little root finder isn’t perfect. It needs a fairly well-behaved target function and/or a good initial guess to work properly. For instance, consider:

```haskell
> solve (\t -> 1/t-2) 1;
0.00205230175365927
```

Here `solve` didn’t find the real root at 0.5 at all. In fact, if you print the solution candidates then you will find that `solve` converges rather slowly in this case and thus bails out after 20 iterations before a good solution is found. Increasing the `nmax` value fixes this:

```haskell
> let nmax = 50;
> solve (\t -> 1/t-2) 1;
0.5
```

There are other pathological cases where the algorithm performs even more poorly. Further improvements of the method presented here can be found in textbooks on numeric algorithms; the interested reader may want to cut his teeth on these algorithms by translating them to Pure in the way we’ve shown here.

### The Same-Fringe Problem

This is one of the classical problems in functional programming which has a straightforward recursive solution, but needs some thought if we want to solve it in an efficient way. Consider a (rooted, directed) tree consisting of branches and leaves. To keep things simple, we may represent these structures as nested lists, e.g.:

```haskell
let t1 = [[a,b],c,[[d]],e,[f,[g,h]]];
let t2 = [a,b,c,[[d],[],e],[f,[g,h]]];
let t3 = [[a,b],[c],[[]],e,[f,[g,h]]];
```

Thus each inner node of the tree is represented as a list containing its (zero or more) subtrees, and the leaves are the “atomic” (non-list) elements. The `fringe` of such a structure is the list of all leaves in left-to-right order, which can be computed as follows:
fringe t = if listp t then catmap fringe t else [t];

Note that listp is a predicate which decides whether its argument is a (proper or improper) list and the catmap function applies the given function to a list, like map, and concatenates all the resulting lists, like cat. Thus, if the argument t is an “atom” (leaf) then fringe simply returns [t], otherwise it recursively applies itself to all the subtrees and concatenates the results:

> fringe t1;
[a,b,c,d,e,f,g,h]
> fringe t2;
[a,b,c,d,e,f,g,h]
> fringe t3;
[a,b,d,c,e,f,g,h]

Note that t1 and t2 differ in structure but have the same fringe, while t1 and t3 have the same structure but different fringes. The problem now is to decide, given any two trees, whether they have the same fringe. Of course, we can easily solve this by just computing the fringes and comparing them with ‘===’ (note that we employ syntactic equality here which also allows us to compare symbols, for which ‘==’ isn’t normally defined):

> fringe t1 === fringe t2;
1
> fringe t3 === fringe t2;
0

However, this is rather inefficient since we always have to fully construct the fringes which may need considerable extra time and space if the trees are large. Most of this effort may be completely wasted if we only need to inspect a tiny fraction of the fringes to find out that they’re different, as in the case of t2 and t3. Also note that our version of the fringe function isn’t tail-recursive and we may thus run into stack overflows for large trees.

This problem, while posed in an abstract way here, is not only of academic interest. For instance, trees may be used as an alternative string data structure which implements concatenation in constant time by just delaying it. In this case we certainly don’t want to explicitly carry out all those concatenations in order to decide whether two such objects are the same.

Therefore, this problem has been studied extensively and more efficient approaches have been developed. One way to solve the problem involves the technique of continuation passing which is a generalization of the accumulating parameter technique we already discussed. It never constructs any part of the fringes explicitly and also works in constant stack space. The algorithm can be implemented in Pure as follows. (This is a slightly modified transliteration of a Lisp program given in Henry Baker’s article “Iterators: Signs of Weakness in Object-Oriented Languages”, ACM OOPS Messenger 4(3), 1993, pp. 18-25, which is also available from Henry Baker’s Archive of Research Papers.)

```plaintext
samefringe t1 t2 =
samefringe (\c -> genfringe t1 c done) (\c -> genfringe t2 c done) with
done c = c [] done;
samefringe g1 g2 =
```

1.5.8 Recursion
As Baker admits himself, this style of programming isn’t “particularly perspicuous”, so we’ll explain the algorithm in a moment. But first let us verify that the program indeed works as advertised. It’s helpful to print out the actual comparisons performed in the innermost lambda in the definition of the local \texttt{samefringe} function, which can be done by adding a little debugging statement as follows (this also needs an import clause “\texttt{using system;}” to make the \texttt{printf} function available):

\begin{verbatim}
  samefringe g1 g2 =
  g1 (\x1 g1 -> g2 (\x2 g2 -> x1==x2 && (x1==[] |\ | samefringe g1 g2)));
end
\end{verbatim}

With this we get:

\begin{verbatim}
> samefringe t1 t2;
 a  ==  a?
 b  ==  b?
 c  ==  c?
 d  ==  d?
 e  ==  e?
 f  ==  f?
 g  ==  g?
 h  ==  h?
 []  ==  []?
 1
\end{verbatim}

So in this case we do a complete traversal of both trees which is the best that we can hope for if the fringes are the same. Note that the final comparison \texttt{[]} \texttt{==} \texttt{[]} ensures that we also hit the end of the two fringes at the same time. This test deals with the corner case that one fringe is a prefix of the other. For instance:

\begin{verbatim}
> let t4 = [[a,b],[c],[[d]],e,[f,[[g,h,i]]]];
> samefringe t4 t2;
 a  ==  a?
 b  ==  b?
 c  ==  c?
 d  ==  d?
 e  ==  e?
 f  ==  f?
 g  ==  g?
 h  ==  h?
 i  ==  []?
 0
\end{verbatim}

Things go a bit differently, however, when comparing \texttt{t3} and \texttt{t2}; as soon as we hit the first discrepancy between the two fringes, the algorithm bails out and correctly asserts that the fringes are different:
Let’s take a closer look at the various parts of the algorithm now. First, the \texttt{genfringe} function:

\begin{verbatim}
> samefringe t3 t2;
a === a?
b === b?
d === c?
0
\end{verbatim}

This routine generates the fringe of a tree, given as the first argument, on the fly. The second argument \texttt{c} (the “consumer”) is a function which gets invoked on the current leaf, to do any required processing. (As we’ll see later, it may also get invoked with the special “sentinel” value \texttt{[]} to indicate the end of the fringe.)

The third argument \texttt{g} (the “generator”) is a \texttt{continuation}, a kind of “callback function” to be invoked \texttt{after} the current subtree has been traversed, in order to process the remainder of the tree. It takes the consumer function \texttt{c} as its sole argument. Consequently, \texttt{genfringe} simply invokes the continuation \texttt{g} on the consumer \texttt{c} when applied to an empty subtree \texttt{[]}\texttt{,} i.e., if there aren’t any leaves to be processed. This case is handled in the first equation for \texttt{genfringe}.

The second equation for \texttt{genfringe} is the interesting one where the recursion happens. It deals with a nonempty tree \texttt{x:t} by invoking itself recursively on \texttt{x}, setting up a new continuation \texttt{\lambda c . genfringe t c g}, which will take care of processing the rest of the subtree \texttt{t}, after which it chains to the previous continuation \texttt{g} which will handle the rest of the tree.

The third equation for \texttt{genfringe} handles the case of a non-list argument, i.e., a leaf. In this case we just pass the leaf \texttt{x} to the consumer function \texttt{c} along with the continuation \texttt{g}. The consumer processes \texttt{x} as needed and may then decide to call the continuation \texttt{g} on itself in order to continue processing the rest of the tree, or simply bail out, returning any value. Note that this entire process is tail-recursive, as long as \texttt{c} chains to \texttt{g} as the last call. It thus only needs constant stack space in addition to what \texttt{c} itself uses.

Note that we need an initial continuation \texttt{g} to get the process started. This is provided by the \texttt{done} function:

\begin{verbatim}
> done c = c [] done;
\end{verbatim}

As we’ve defined it, \texttt{done} invokes the consumer \texttt{c} on an empty list to signal the end of the fringe. For good measure, it also passes itself as the continuation argument; however, normally the consumer will never use this argument and just bail out when invoked on the \texttt{[]} value.

To see how this works, we can just enter \texttt{done} and \texttt{genfringe} as global functions and invoke them on a suitable consumer function, e.g.
In the case of samefringe, we use the local samefringe function as our consumer instead. This works pretty much the same, except that samefringe employs two continuations \(g_1\) and \(g_2\) to traverse both trees at the same time:

\[
\text{samefringe } g_1 g_2 =
\text{ \ g1 } (\lambda x1 \ g1 \rightarrow g2 (\lambda x2 \ g2 \rightarrow x1=x2 && (x1=\[] || \text{samefringe } g1 g2));
\]

Note that the outer lambda \(\lambda x1 \ g1 \rightarrow\ldots\) becomes the consumer for the first generator \(g1\) which traverses \(t1\). When called, it then invokes the second generator \(g2\), which traverses \(t2\), on the consumer (inner lambda) \(\lambda x2 \ g2 \rightarrow \ldots\). This in turn does the necessary tests to verify that the current leaf elements are the same, or to bail out from the recursion if they aren’t or if we reached the end of the fringes. Also note that this is still tail-recursive because the short-circuit logical operations \(&&\) and \(||\) are both tail-recursive in their second operand (cf. Stack Size and Tail Recursion).

### 1.5.9 Higher-Order Functions

As we have seen, functions are first-class citizens in Pure which can be created on the fly (using partial applications as well as lambdas and local functions), assigned to variables and passed around freely as function arguments and results. Thus it becomes possible to define higher-order functions which take other functions as arguments and/or return them as results. This is generally considered a hallmark feature of functional programming, and much of the power of functional programming stems from it. In fact, higher-order functions are so deeply ingrained in the modern functional programming style that you’ll hardly find a nontrivial program that doesn’t use them in some way, and we have already seen many examples of them throughout the manual. While most imperative programming languages today let you treat functions as values, too, they’re typically much more limited in the ways that new functions can be created dynamically. Only recently have partial application and anonymous closures arrived in some mainstream imperative languages, and they are often still rather awkward to use.

The simplest case of a higher-order function is a function which takes another function as an argument. For instance, we have seen the function \(\text{map}\) which applies a function to each member of a list. If it wasn’t in the prelude, it could be defined as follows:

\[
\begin{align*}
\text{map } f \ [\] & = \ []; \\
\text{map } f \ (x:xs) & = f \ x : \text{map } f \ xs;
\end{align*}
\]

(Note that this isn’t the actual definition from the prelude, which goes to some lengths to make the operation tail-recursive and properly handle lazy lists. But we won’t dive into these technicalities here since we’re only interested in the higher-order aspect right now.)
This definition is rather straightforward: To map a function \( f \) to a list, just apply it to the head element \( x \) and recurse into the tail \( xs \). The recursion stops at the empty list which is returned as is. For instance:

\[
> \text{map} \ (*2) \ (0..10);
[0,2,4,6,8,10,12,14,16,18,20]
\]

The prelude includes an entire collection of such generic list functions which have proven their utility as basic building blocks for many list processing tasks. We’ll have a closer look at these later, see List Processing.

Another numerical example is the function \( \text{derive} \) which we used in our root finder example to calculate the difference quotient of a function \( f \) at a given point \( x \):

\[
\text{derive} \ f \ x = (f \ (x+dx) - f \ x) / dx;
\]

This example is also interesting because we can turn \( \text{derive} \) into a function mapping functions to other functions, by partially applying it to the target function. So we may write:

\[
> \text{let} \ dx = 1e-8;
> \text{map} \ (\text{derive square}) \ (1..4) \ \text{with} \ square \ x = x*x \ \text{end};
[1.99999998784506,3.99999997569012,5.99999996353517,7.99999995138023]
\]

This illustrates an easy way to create new functions from existing ones: partial application. (In fact we also did that when we applied the operator section \( (*2) \) using \text{map} above. Note that \( (*2) \) is a function which doubles its single argument.) This simple recipe is surprisingly powerful. For instance, the prelude defines the function composition operator ‘.’ as:

\[
(f.g) \ x = f \ (g \ x);
\]

The partial application \( f.g \) thus applies two given functions \( f \) and \( g \) in sequence (first \( g \), then \( f \)). Functions of this kind, which create new functions by combining existing ones, are also known as combinators. For instance, using ‘.’ we can easily create a function which “clamps” its argument between given bounds by just combining the \( \text{min} \) and \( \text{max} \) functions from the prelude as follows:

\[
> \text{clamp} \ a \ b = \text{max} \ a \ . \ \text{min} \ b;
> \text{map} \ (\text{clamp} \ (-3) \ 3) \ (-5..5);
[-3,-3,-3,-2,-1,0,1,2,3,3]
\]

Note that partial application works with constructor symbols, too:

\[
> \text{map} \ (0:) \ [1..3,4..6,7..9];
[[0,1,2,3],[0,4,5,6],[0,7,8,9]]
\]

Another more direct way to define combinators is to make them return a local or anonymous function. For instance, the following equations lift the ‘+’ and ‘-’ operators to pointwise operations:

\[
f + g = \ \lambda x . f x + g x \ \text{if} \ \text{nargs} \ f > 0 \ \&\& \ \text{nargs} \ g > 0;
\]

\[
f - g = \ \lambda x . f x - g x \ \text{if} \ \text{nargs} \ f > 0 \ \&\& \ \text{nargs} \ g > 0;
\]
This employs the `nargs` function from the standard library which returns the argument count of a global or local function. We use this here to check that the operands are defined functions taking at least one argument. The result is a function which applies the function operands to the given argument and computes their sum and difference, respectively. For instance:

```plaintext
> map (f+g-h) (1..10) with f x = 2*x+1; g x = x*x; h x = 3 end;
[1,6,13,22,33,46,61,78,97,118]
```

These rules also handle functions taking multiple arguments, so that you can write, e.g.:

```plaintext
> (max-min) 2 5;
3
```

Constructors can be extended in exactly the same way:

```plaintext
> f,g = \x -> f x, g x if nargs f > 0 && nargs g > 0;
> (max,min,max-min) 2 5;
5,2,3
```

### 1.5.10 List Processing

Pure’s list data structure provides you with a convenient way to represent sequences of arbitrary values. This is one of the few compound data structures which has built-in support by the compiler, so that some syntactic sugar is available which allows you to express certain list operations in a convenient way. But for the most part, lists are implemented in the prelude just like any other data structure.

The empty list is denoted `[]`, and compound lists can be put together in a right-recursive fashion using the ‘:’ operator. The customary bracketed notation is provided as well, and this is also the syntax the interpreter normally uses to print list values:

```plaintext
> 1:2:3:[];
[1,2,3]
```

Note that the bracketed notation is just syntactic sugar; internally all list values are represented as right-recursive applications of the ‘:’ operator. Thus it is possible to match the head and tail of a list using a pattern like `x:xs`:

```plaintext
> case [1,2,3] of x:xs = x,xs end;
1,[2,3]
```

Lists can contain any combination of elements (also from different types) and they may also be nested:

```plaintext
> [1,2.0,[x,y],"a string"]; [1,2.0,[x,y],"a string"]
```

List concatenation is denoted `+`, and the `#`, `!` and `!!` operators can be used to compute the length of a list and extract elements and slices of a list using zero-based indexing:

```plaintext
> [a,b,c]+[x,y,z]; [a,b,c,x,y,z]
```
Note that lists are immutable in Pure (just like most of Pure’s built-in and predefined data structures), so there are no operations which modify lists in-place. E.g., concatenation works as if it was defined recursively by the following rules:

\[
[] + ys = ys;
(x:xs) + ys = x : (xs + ys);
\]

So a new list is created which replaces the empty list in the last component of the left operand with the right operand. This even works if the second operand is no list at all, in which case an improper list value is produced:

\[
[a,b,c] + y;
\]

These can be useful, e.g., to represent symbolic list values. Note that a **proper** list value contains the empty list \([]\) in its rightmost component; an **improper** list value is one which doesn’t. There are some list functions like `reverse` which really need proper lists to work and will throw an exception otherwise, but many predefined operations will deal with improper lists just fine:

\[
\]

Arithmetic sequences are denoted with the .. operator:

\[
1..10; 10:9..1; 0.0:0.1..1.0;
\]

List comprehensions provide another way to construct (proper) list values using a convenient math-like notation:

\[
[2^x \mid x = 1..10];
\]

We’ll discuss this construct in more detail later, see List Comprehensions.

The prelude provides a fairly comprehensive collection of useful list functions, including some powerful generic operations which let you do most common list manipulations with ease. For instance, we have already seen the `map` function:

\[
\]

1.5.10 List Processing
There’s also a function `do` which works in the same fashion but throws away all the results and simply returns `()`. Of course this makes sense only if the applied function has some interesting side-effect. E.g., here’s a quick way to print all members of a list, one per line. This combines the `str` function (which converts any Pure expression to its printable representation, cf. String Processing below) with the `puts` function from the `system` module (which is just the corresponding C function, so it prints a string on the terminal, followed by a newline).

```pure
> using system;
> do (puts.str) (1..3);
1 2 3 ()
```

Another useful list function is `filter` which applies a predicate to each member of a list and collects all list elements which satisfy the predicate:

```pure
> odd x = x mod 2; even x = ~odd x;
> filter odd (1..20);
[1,3,5,7,9,11,13,15,17,19]
> filter even (1..20);
[2,4,6,8,10,12,14,16,18,20]
```

In addition, the `all` and `any` functions can be used to check whether all or any list elements satisfy a given predicate:

```pure
> any even (1:3..20);
0
> all odd (1:3..20);
1
```

There’s also a family of functions such as `foldl` which generalize the notion of aggregate functions such as list sums and products. Starting from a given initial value `a`, `foldl` iterates a binary function `f` over a list `xs` and returns the accumulated result. It’s defined as follows:

```pure
dfoldl f a [] = a;
dfoldl f a (x:xs) = foldl f (f a x) xs;
```

For instance, we can use `foldl` to compute list sums and products:

```pure
> foldl (+) 0 (1..10);
55
> foldl (*) 1 (1..10);
3628800
```

Note that `foldl` (“fold-left”) accumulates results from left to right, so the result accumulated so far is passed as the `left` argument to the function `f`. There’s a `foldr` (“fold-right”) function which works analogously but collects results from right to left, and accordingly passes the accumulated result in the `right` argument. Usually this won’t make a difference if the iterated function is associative, but `foldl` and `foldr` have lots of applications beyond these simple use cases. For instance, we may use `foldl` to reverse a list as follows:
> foldl (flip (:)) [] (1..10);
[10,9,8,7,6,5,4,3,2,1]

Note that we have to flip the arguments of the ‘:’ constructor here, since foldl passes the accumulated list in the left argument, but ‘:’ wants it on the right. Conversely, we have that:

> foldr (:) [] (1..10);
[1,2,3,4,5,6,7,8,9,10]

This just returns the list unchanged. So the order in which we accumulate results does matter here.

In a similar fashion, we might use foldl (or foldr) to build any kind of compound data structure from a list of its members. For instance, recall our binary tree example:

```
nonfix nil;
insert nil y = bin y nil nil;
insert (bin x L R) y = bin x (insert L y) R if y<x;
          = bin x L (insert R y) otherwise;
```

We can then use foldl insert to construct a binary tree from its member list as follows:

> foldl insert nil [7,12,9,5];
bin 7 (bin 5 nil nil) (bin 12 (bin 9 nil nil) nil)

Sometimes we’d like to know not just the final result of an aggregate function, but all the intermediate results as well. The scanl function does this. For instance:

> scanl (+) 0 (1..10);
[0,1,3,6,10,15,21,28,36,45,55]

Note that this computes the same list of partial sums as:

> [foldl (+) 0 (1..n) | n = 0..10];
[0,1,3,6,10,15,21,28,36,45,55]

However, the former is more efficient since it does all the partial sums in one go.

Like foldl, scanl also has a sibling called scanr which collects results from right to left, starting at the end of the list:

> scanr (+) 0 (1..10);
[55,54,52,49,45,40,34,27,19,10,0]

Another useful list generation function is iterwhile which keeps applying a function starting at a given initial value, as long as the current value satisfies the given predicate. So another way to generate the odd numbers up to 20 is:

> iterwhile (<=20) (+2) 1;
[1,3,5,7,9,11,13,15,17,19]

Or we might collect all powers of 2 which fall into the 16 bit range:
> iterwhile (<0x10000) (+2) 1;
[1,2,4,8,16,32,64,128,256,512,1024,2048,4096,8192,16384,32768]

There are also various functions to partition a list into different parts according to various criteria. The simplest of these are the head and tail functions:

> let xs = 1..10;
> head xs; tail xs;
1
[2,3,4,5,6,7,8,9,10]

Conversely, the last and init functions give you the last element of a list, and all but the last element, respectively:

> last xs; init xs;
10
[1,2,3,4,5,6,7,8,9]

The take and drop functions take or remove a given number of initial elements, while takewhile and dropwhile take or remove initial elements while a given predicate is satisfied:

> take 4 xs; drop 4 xs;
[1,2,3,4]
[5,6,7,8,9,10]
> takewhile (<=4) xs; dropwhile (<=4) xs;
[1,2,3,4]
[5,6,7,8,9,10]

Lists can be reversed with reverse and sorted using sort:

> reverse xs;
[10,9,8,7,6,5,4,3,2,1]
> sort (<) (xs + ans);
[1,1,2,2,3,3,4,4,5,5,6,6,7,7,8,8,9,9,10,10]

You can also concatenate a list of lists with the cat function:

> cat [1..n | n = 1..5];
[1,1,2,1,2,3,1,2,3,4,1,2,3,4,5]

Last but not least, there is the zip family of functions which let you combine members of two or more lists in different ways. The zip function itself collects pairs of corresponding elements in two input lists:

> zip (1..5) ("a".."e");
[(1,"a"),(2,"b"),(3,"c"),(4,"d"),(5,"e")]

The effect of zip can be undone with unzip which returns a pair of lists:

> unzip ans;
[1,2,3,4,5],["a","b","c","d","e"]
The `zipwith` function is a generic version of `zip` which combines corresponding members from two lists using a given binary function `f`:

```haskell
> zipwith (+) (1..10) (1..10);
[1,4,9,16,25,36,49,64,81,100]
```

You might also consider `zipwith` a variant of `map` working with two lists at the same time (in fact this operation is also known as `map2` in some functional programming languages). There are also variations of these functions which work with three lists (`zip3`, `unzip3`, `zipwith3`).

Note that `zip` itself is equivalent to `zipwith (,)`:

```haskell
> zipwith (,) (1..5) ("a".."e");
[(1,"a"),(2,"b"),(3,"c"),(4,"d"),(5,"e")]
```

Also note that since tuples are formed by just applying the `,'` operator repeatedly, you can use multiple calls of `zip` to piece together tuples of any length:

```haskell
> zip (1..3) (zip ("a".."c") [a,b,c]);
[(1,"a",a),(2,"b",b),(3,"c",c)]
```

This can be achieved even more easily by folding `zip` over a list of lists; here we employ a variation `foldr1` of `foldr` which takes the initial value from the beginning of the list.

```haskell
> foldr1 zip [1..3,"a".."c",[a,b,c]];
[(1,"a",a),(2,"b",b),(3,"c",c)]
```

Note that this method easily scales up to as many element lists as you want. Recovering the original element lists is a bit trickier, though, but it can be done using this little helper function:

```haskell
unzipn n xs = xs if n<=1;
= xs,unzipn (n-1) ys when xs,ys = unzip xs end otherwise;
```

For instance:

```haskell
> foldr1 zip [1..3,"a".."c",[a,b,c]];
[(1,"a",a),(2,"b",b),(3,"c",c)]
> unzipn 3 ans;
[1,2,3],["a","b","c"],[a,b,c]
```

Also, the elements to be zipped don’t have to be singletons, they can themselves be tuples of any size:

```haskell
> foldr1 zip [[1,2,3],[a,(),c],[x,y,(z,t)]];
[(1,a),(2,y),(3,c,z,t)]
```

But note that in this case you lose the information which elements came from which sub-lists, so `unzip` won’t be able to recover the original lists any more. If you need to avoid that then it’s best to use other aggregates such as lists or vectors for the sublist elements.

There are other interesting list functions in the prelude, but we’ll leave it at that for now. Please check the `Pure Library Manual` for a full account of the available operations.
1.5.11 String Processing

Let's take a short break from lists and look at strings. We postponed that until now since strings are in many ways just like lists of characters. In fact the similarities run so deep that in some languages, most notably Haskell, strings are in fact just lists. Pure doesn’t go quite that far; it still represents strings as null-terminated arrays of characters in the UTF-8 encoding, which is a much more compact representation and eases interoperability with C. However, most common list operations also work on strings in an analogous fashion. Thus you can concatenate strings, compute their length, and index, slice and compare them as usual:

```plaintext
> "abc" + "xyz";
"abcxyz"
> #ans, ans!5, ans!![2,3];
6,"z","cx"
> "abc" == "abd";
0
```

In addition, strings can also be ordered lexicographically:

```plaintext
> "abd" < "abcd";
0
> "abd" > "abcd";
1
> sort (<) ["the", "little", "brown", "fox"];
["brown", "fox", "little", "the"]
```

Where it makes sense, list operations on strings return again a string result:

```plaintext
> head "abc"; tail "abc";
"a" "bc"
> take 4 "abcdefg"; drop 4 "abcdefg";
"abcd" "efg"
```

A slight complication arises with the `map` function, because in this case the result is not guaranteed to be a string in all cases. For instance:

```plaintext
> map ord "HAL";
[72,65,76]
```

To have `map` work consistently, it will thus yield a list even in cases where the result could again be represented as a string. If you want a string result instead, you’ll have to do the conversion explicitly, using the `string` function:

```plaintext
> map (+1) "HAL";
["I","B","M"]
> string ans;
"IBM"
```

Conversely, you can also convert a string to a list of its characters using either `chars` or the generic `list` conversion function:
As in the case of \texttt{map}, this conversion is usually done automatically if a list operation from the prelude is applied to a string. This also happens if a list comprehension draws values from a string:

\begin{verbatim}
> [x-1 | x = "IBM"];
["H","A","L"]
\end{verbatim}

Talking about characters, these are simply single character strings, so Pure has no separate data type for them. However, there is a type tag \texttt{char} for the single character strings which can be used in pattern matching:

\begin{verbatim}
> isupper x::char = "A"<=x && x="Z";
> filter isupper "The Little Brown Fox"; "TLBF"
> any isupper "The Little Brown Fox"; 1
\end{verbatim}

Maybe you wondered how that "HAL" => "IBM" transformation above came about? Well, the prelude also defines basic arithmetic on characters:

\begin{verbatim}
> "a"+1, "a"+2, "z"-1;
"b", "c", "y"
> "z"-"a";
25
\end{verbatim}

This considers characters as an enumerated data type where each character corresponds to a numeric code point in Unicode. Hence, e.g., "a"+1 gives "b" because "b" is the code point following "a" in Unicode, and "b"-"a" gives 1 for the same reason.

So here’s the \texttt{rot13} encoding in Pure:

\begin{verbatim}
rot13 x::string = string (map rot13 x) with
  rot13 c = c+13 if "a" <= lower c && lower c <= "m";
  = c-13 if "n" <= lower c && lower c <= "z";
  = c otherwise;
lower c = "a"+(c-"A") if "A"<=c && c="Z";
  = c otherwise;
end;
\end{verbatim}

For instance:

\begin{verbatim}
> rot13 "The quick brown fox";
"Gur dhvpx oebja sbk"
> rot13 ans;
"The quick brown fox"
\end{verbatim}

Character arithmetic also makes arithmetic sequences of characters work as expected:

\begin{verbatim}
> "a".."k"; "k";"j"..'a";
["a","b","c","d","e","f","g","h","i","j","k"]
\end{verbatim}
You can also convert between characters and their ordinal numbers using the `ord` and `chr` functions:

```pure
> ord "a";
97
> chr (ans+1);
"b"
```

Thus using Horner’s rule we might convert a string of decimal digits to its numeric representation as follows:

```pure
> foldl (\x c -> 10*x+ord c-ord "0") 0 "123456";
123456
```

However, there are much easier and more general ways to convert between strings and Pure expressions. Specifically, `val` and `str` can be used to convert between any Pure value and its string representation:

```pure
> val "2*(3+4)"; str ans;
2*(3+4)
"2*(3+4)"
```

If you also want to evaluate the string representation of a Pure expression then `eval` is your friend:

```pure
> eval "2*(3+4)";
14
```

Two other convenient functions are `split` which breaks apart a string at a given delimiter string, and `join` which concatenates a list of strings, interpolating the delimiter string between successive list elements:

```pure
> split " " "The quick brown fox";
["The","quick","brown","fox"]
> join ":" ans;
"The:quick:brown:fox"
```

If you don’t need the intervening delimiters then you can also concatenate string lists simply with `strcat`:

```pure
> strcat ["The","quick","brown","fox"];
"Thequickbrownfox"
```

These operations are all implemented in an efficient way so that they run in linear time. (Note that the `string` conversion function we mentioned above is in fact just `strcat` on lists of strings, but it also works with other aggregates such as vectors of strings.)

For more elaborate needs there’s also a suite of functions for doing regular expression matching in the `regex` module, and the `system` module provides the usual facilities for reading and
writing strings from/to text files and the terminal, as well as the `printf` and `scanf` family of functions which are used to print and parse strings according to a given format string. These are all explained in detail in the *Pure Library Manual*.

### 1.5.12 List Comprehensions

List comprehensions are Pure’s main workhorse for generating and processing all kinds of list values. You can think of them as a combination of `map` and `filter` using a prettier syntax reminiscent of the way in which sets are commonly specified in mathematics. List comprehensions are in fact just syntactic sugar, so anything that can be done with them can also be accomplished with Pure’s generic list functions; but often they are much easier to write and understand.

In the simplest case, list comprehensions are just a shorthand for `map` with lambdas:

```haskell
> [2*x-1 | x = 1..10];
[1,3,5,7,9,11,13,15,17,19]
```

This can be read aloud as “the list of all $2\times x-1$ for which $x$ runs through the list $1..10$”. The part $x = 1..10$ is called a **generator clause**. The comprehension binds $x$ to each member of the list $1..10$ in turn and evaluates the target expression $2\times x+1$ in the context of this binding. This is equivalent to the following `map` expression:

```haskell
> map (\x->2*x-1) (1..10);
[1,3,5,7,9,11,13,15,17,19]
```

List comprehensions may also involve **filter clauses**: predicates which determine the elements that are to be included in the result list.

```haskell
> [2*x-1 | x = 1..10; x mod 3];
[1,3,7,9,13,15,19]
```

This can be read as “the list of all $2\times x-1$ for which $x$ runs through $1..10$ and for which $x \mod 3$ is non-zero” (which means that $x$ is not a multiple of 3). It is roughly equivalent to:

```haskell
> map (\x->2*x-1) (filter (\x->x mod 3) (1..10));
[1,3,7,9,13,15,19]
```

List comprehensions can also draw values from other kinds of aggregates such as strings and matrices, but the result is always a list:

```haskell
> [x-1 | x = "IBM"];
["H","A","L"]
> [1/x | x = {1,2,3;4,5,6}; ~x mod 2];
[0.5,0.25,0.1666666666666667]
```

List comprehensions can have as many generator and filter clauses as you want. The clauses are considered in left-to-right order so that later clauses may refer to any variables introduced in earlier generator clauses. E.g., here’s how you can generate the list of all pairs $(i,j)$ with $1\leq i\leq j\leq 5$ such that $i+j$ is even:

```haskell
> [(i,j) | i = 1..5; j = i..5; i+j mod 2];
[(1,1),(1,3),(1,5),(2,2),(2,4),(3,3),(3,5),(4,4)]
```
The left-hand side of a generator clause can be an arbitrary pattern, which is useful if you need to peek at the list elements to see what’s inside. For instance, let’s take the previous result and check that the sums of the number pairs are in fact all even:

> [i+j | i,j = ans];
[2,4,6,6,6,8,8,10]

Generator clauses involving patterns also act as filters; unmatched elements are filtered out automatically:

> [i+j | i,j = ["to be ignored",(1,1),(2,2),3]];
[2,4]

List comprehensions can also be nested to an arbitrary depth. For instance, we may rewrite the “even sums” comprehension from above as follows, in order to group the pairs into sublists for each value of \(i\):

> [[i,j | j = i..5; ~(i+j) mod 2] | i = 1..5];

A notorious example is the following recursive algorithm which implements a variation of Erathosthenes’ classical prime sieve. (This method is actually rather slow and thus not suitable for computing large primes, but we’re not concerned with that here.)

```plaintext
primes n = sieve (2..n) with
  sieve [] = [];
  sieve (p:qs) = p : sieve [q | q = qs; q mod p];
end;
```

Note that the sieve recursively filters out the multiples of the current front element \(p\) of the list, which, by virtue of the construction, is always a prime number. The result is the list of all primes up to \(n\):

> primes 100;

List comprehensions are also a useful device to organize backtracking searches. For instance, here’s an algorithm for the \(n\) queens problem, which returns the list of all placements of \(n\) queens on an \(n\times n\) board (encoded as lists of \(n\) pairs \((i,j)\) with \(i = 1..n\)), so that no two queens hold each other in check:

```plaintext
queens n = search n 1 [] with
  search n i p = [reverse p] if i=n;
  = cat [search n (i+1) ((i,j):p) | j = 1..n; safe (i,j) p];
  safe (i,j) p = ~any (check (i,j)) p;
  check (i1,j1) (i2,j2)
    = i1==i2 || j1==j2 || i1+j1==i2+j2 || i1-j1==i2-j2;
end;
```
1.5.13 Lazy Evaluation and Streams

As already mentioned, lists can also be evaluated in a “lazy” fashion, by just turning the tail of a list into a future. This special kind of list is also called a stream. Streams enable you to work with infinite lists (or finite lists which are so huge that you would never want to keep them in memory in their entirety). E.g., here’s one way to define the infinite stream of all Fibonacci numbers:

```
> let fibs = fibs 0L 1L with fibs a b = a : fibs b (a+b) & end;
> fibs;
0L:<thunk 0xb5d54320>
```

Note the & on the tail of the list in the definition of the local fibs function. This turns the result of fibs into a stream, which is required to prevent the function from recursing into samadhi. Also note that we work with bigints in this example because the Fibonacci numbers grow quite rapidly, so with machine integers the values would soon start wrapping around to negative integers.

Streams like these can be worked with in pretty much the same way as with lists. Of course, care must be taken not to invoke “eager” operations such as # (which computes the size of a list) on infinite streams, to prevent infinite recursion. However, many list operations work with infinite streams just fine, and return the appropriate stream results. E.g., the take function (which retrieves a given number of elements from the front of a list) works with streams just as well as with “eager” lists:

```
> take 10 fibs;
0L:<thunk 0xb5d54350>
```

Hmm, not much progress there, but that’s just how streams work (or rather they don’t, they’re lazy bums indeed!). Nevertheless, the stream computed with take is in fact finite and we can readily convert it to an ordinary list, forcing its evaluation:

```
> list (take 10 fibs);
[0L,1L,1L,2L,3L,5L,8L,13L,21L,34L]
```

An alternative way to achieve this is to cut a “slice” from the stream:

```
> fibs!!(0..10);
[0L,1L,1L,2L,3L,5L,8L,13L,21L,34L,55L]
```

Note that since we bound the stream to a variable, the already computed prefix of the stream has been memoized, so that this portion of the stream is now readily available in case we need to have another look at it later. By these means, possibly costly reevaluations are avoided, trading memory for execution speed:

```
> fibs;
0L:1L:1L:2L:3L:5L:8L:13L:21L:34L:55L:<thunk 0xb5d54590>
```

The prelude also provides some convenience operations for generating stream values. Infinite arithmetic sequences are specified using inf or -inf to denote an upper (or lower) infinite bound for the sequence, e.g.:
> let u = 1..inf; let v = -1.0:-1.2..-inf;
> u!!!(0..10); v!!!(0..10);
[1,2,3,4,5,6,7,8,9,10,11]
[-1.0,-1.2,-1.4,-1.6,-1.8,-2.0,-2.2,-2.4,-2.6,-2.8,-3.0]

Other useful stream generator functions are \texttt{iterate}, which keeps applying the same function over and over again, \texttt{repeat}, which just repeats its argument forever, and \texttt{cycle}, which cycles through the elements of the given list:

> iterate (*2) 1!!!(0..10);
[1,2,4,8,16,32,64,128,256,512,1024]
> repeat 1!!!(0..10);
[1,1,1,1,1,1,1,1,1,1,1]
> cycle [0,1]!!!(0..10);
[0,1,0,1,0,1,0,1,0,1,0]

Moreover, list comprehensions can draw values from streams and return the appropriate stream result:

> let rats = [m,n-m | n=2..inf; m=1..n-1; gcd m (n-m) == 1]; rats;
(1,1):<thunk 0xb5d54950>
> rats!!(0..10);
[(1,1),(1,2),(2,1),(1,3),(3,1),(1,4),(2,3),(3,2),(4,1),(1,5),(5,1)]

We can also rewrite our prime sieve so that it generates the infinite stream of all prime numbers:

\begin{verbatim}
all_primes = sieve (2..inf) with
  sieve (p:qs) = p : sieve [q | q = qs; q mod p] &;
end;
\end{verbatim}

Note that we can omit the empty list case of \texttt{sieve} here, since the sieve now never becomes empty. Example:

> let P = all_primes;
> P!!(0..20);
[2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,53,59,61,67,71,73]
> P!299;
1987

You can also just print the entire stream. Note that this sieve algorithm isn’t tail-recursive, so the following will eventually result in a stack overflow. But this will take a while, so you may want to hit Ctrl-c when you get bored:

> using system;
> do (printf "%d\n") all_primes;
2
3
5
...

It’s also possible to convert an ordinary list to a stream:
This may seem like a silly thing to do, because the original list is already fully known beforehand. But this transformation allows us to traverse the list in a lazy fashion, which can be useful if the list is employed in a list comprehension or processed by functions such as `cat` and `map`. For instance, we can use this to rewrite the `fringe` function from The Same-Fringe Problem so that it calculates the fringe in a lazy fashion:

```haskell
lazyfringe t = if listp t then catmap lazyfringe (stream t) else [t];
```

Recall that the fringe of a tree is the list of its leaves in left-to-right order. The tree itself is represented as a nested list, to which `lazyfringe` applies `stream` recursively so that the fringe becomes a stream whose elements are only produced on demand:

```haskell
> lazyfringe [[a,b],c,[[d]],e,[f,[[g,h]]]];  
"a:b:d:"#thunk 0x7fd308116060>  
> list ans;  
[a,b,c,d,e,f,g,h]
```

Hence a simple syntactic equality check now suffices to solve the same-fringe problem in an efficient way. For instance, consider the following sample trees from The Same-Fringe Problem:

```haskell
let t1 = [[a,b],c,[[d]],e,[f,[[g,h]]]];  
let t2 = [a,b,c,[[d],[],e],[f,[g,[h]]]];  
let t3 = [[a,b],[d,[[c]],e],[f,[[g,h]]]];  
```

Let’s also bind the fringes to some variables so that we can check which parts actually get evaluated:

```haskell
let l1 = lazyfringe t1;  
let l2 = lazyfringe t2;  
let l3 = lazyfringe t3;  
```

Now comparing `l3` and `l2` we get:

```haskell
> l3 == l2; l3; l2;  
0  
a:b:d:#thunk 0x7fd308116178>  
a:b:c:#thunk 0x7fd308116060>
```

As you can see, the two fringes were only constructed as far as needed to decide that they differ. Of course, if we compare `l1` and `l2` then the fringes will still be fully constructed before we find that they’re equal:

```haskell
> l1 == l2; l1; l2;  
1  
[a,b,c,d,e,f,g,h]  
[a,b,c,d,e,f,g,h]
```

But this doesn’t really matter if we construct the fringes as temporary values, as in:

```
1.5.13 Lazy Evaluation and Streams 109
fringe t1 === fringe t2;

Now only the parts of the fringes are in memory which are currently under scrutiny as the ‘===’ operator passes over them; the prefixes which have already been found to be equal can be garbage-collected immediately. Moreover, the ‘===’ operator is tail-recursive so that the entire equality test can be executed in constant stack space. This gives us an easier way to solve the same-fringe problem which has pretty much the same benefits as our earlier solution using continuations. The latter might still be considered more elegant, because it works without actually constructing the fringes at all. But the solution using lazy evaluation is certainly much simpler.

1.5.14 Matrices and Vectors

Pure has a versatile matrix data structure offering compact storage and efficient random access to its members. Pure matrices work pretty much like in MATLAB or Octave, except that indexes are zero-based and elements are stored in C’s row-major rather than Fortran’s column-major format. They are also binary-compatible with the GNU Scientific Library (GSL) so that they can readily be passed to GSL functions for doing numeric calculations.

Pure offers a number of basic matrix operations, such as matrix construction, pattern matching, indexing, slicing, as well as getting the size and dimensions of a matrix. It does not supply built-in support for matrix arithmetic and other linear algebra algorithms, but it’s easy to roll your own if desired, as we’ll see below. (Usually this won’t offer the same performance as the GSL and other carefully optimized C and Fortran routines, however. So if you need to do some heavy-duty number crunching then you might want to take a look at the pure-gsl module available at the Pure website, which is an ongoing project to make the GSL functions available in Pure.)

Matrices are denoted using curly braces in Pure:

> let x = {1,2,3;4,5,6}; x;
{1,2,3;4,5,6}

Note that the semicolon is used to separate different rows, while the elements inside each row are separated with commas. Thus the above denotes a 2x3 matrix (2 rows, 3 columns). The `dim` function lets you check the dimensions, while the ‘#’ operator gives the total number of elements:

> dim x; #x;
2,3
6

There’s no separate data type for vectors; row and column vectors are simply represented as 1 x n and n x 1 matrices, respectively:

> dim {1,2,3}; dim {1;2;3};
1,3
3,1

Singleton and empty matrices can be denoted as follows:
The transpose function turns columns into rows and vice versa; in particular, you can also use this to convert between row and column vectors:

```
> transpose x;
{1,4;2,5;3,6}
> transpose {1,2,3}; transpose {1;2;3};
{1,2,3}
{1;2;3}
```

Note that matrices are immutable in Pure, so matrix functions like `transpose` always return a new matrix, leaving the original matrix unchanged. (If you need to modify matrices in-place for efficiency, then you can use the GSL or other C or Fortran functions.)

You can change the dimensions of a matrix with the `redim` function, provided that the size stays the same. So, for instance, we can turn the matrix `x` into a row vector as follows:

```
> redim (1,6) x;
{1,2,3,4,5,6}
```

Again, this doesn’t change the original matrix, but returns a new matrix with the same contents and the requested dimensions. This operation also allows you to change the dimensions of an empty matrix which, as we’ve seen above, has dimensions 0,0 by default. Of course, this requires that either the number of rows or columns is still zero. For instance:

```
> redim (3,0) {};
{}  
> dim ans;
3,0
```

Another way to do this is to just construct a zero matrix with zero rows or columns directly, see below. (Note that these different kinds of empty matrices are needed to represent the corner cases. E.g., a linear mapping from 3-dimensional vectors to the zero vector space corresponds to a 0x3 matrix which yields a 3x0 matrix when transposed.)

A number of other specific conversion operations are available, such as `rowvector` and `colvector` which convert a matrix to a row or column vector, respectively, or `diag` which extracts the main diagonal of a matrix:

```
> rowvector x;
{1,2,3,4,5,6}
> colvector x;
{1;2;3;4;5;6}
> diag x;
{1,5}
```

You can also extract the rows and columns of a matrix, which yields a list of the corresponding row and column vectors, respectively:
There are a number of other operations which convert between matrices and different kinds of aggregates; please check the *Matrix Functions* section in the *Pure Library Manual* for details.

Element access uses the index operator ‘!’. You can either specify a pair \((i, j)\) of row and column indices, or a single index \(i\) which treats the entire matrix as a single vector in row-major order:

\[
> \text{rows } x; \text{ cols } x; \\
> [\{1,2,3\},\{4,5,6\}] \\
> [\{1\};4,\{2\};5,\{3\};6] \\
\]

Slicing is done with the ‘!!’ operator. The index range can be specified in different ways. First, a pair of lists of row and column indices cuts a rectangular slice from the matrix:

\[
> x!!(0..1,1..2); \\
> \{2,3;5,6\} \\
\]

Second, a pair of a list and a row or column index cuts slices from individual rows or columns:

\[
> x!!(0,1..2); x!!(0..1,2); \\
> \{2,3\} \\
> \{3;6\} \\
\]

Third, a list of pairs of row and column indices, or a list of element indices gives a row vector with all the corresponding elements:

\[
> x!![(0,2),(1,2)]; \\
> \{3,6\} \\
> x!!(2..3); \\
> \{3,4\} \\
\]

While most of the slices above are contiguous (a case which the prelude optimizes for), you can also specify indices in any order, possibly with duplicates. So we may not only cut submatrix slices, but also permute and/or copy rows and columns of a matrix along the way:

\[
> x!!([1,0,1],0..2); \\
> \{4,5,6;1,2,3;4,5,6\} \\
\]

Matrices can also be constructed from submatrices by arranging the submatrices in rows or columns. In fact, the curly braces accept any combination of submatrices and scalars, provided that all dimensions match up:

\[
> \{1,2,3;\{4,5\},6\}; \\
> \{1,2,3;4,5,6\}; \\
> \{(1;4),(2,3;5,6)\}; \\
\]
The end result must be a rectangular matrix, however, otherwise you’ll get an exception indicating a submatrix whose dimensions don’t match:

```plaintext
> {1,{2,3};{4,5}};
<stdin>, line 24: unhandled exception 'bad_matrix_value {4,5}'
while evaluating '{1,{2,3};{4,5}}'
```

This “splicing” of submatrices is especially useful when doing linear algebra, where matrices are often composed from smaller “block matrices” or vectors; we’ll see an example of this later. (Sometimes this behaviour also gets in the way, and thus there are ways to disable it; see Symbolic Matrices below.)

Pure actually provides several different types of numeric matrices, which correspond to the different GSL matrix types for integer, floating point and complex numbers. (Note that complex numbers aren’t a built-in data type in Pure, but there are ways to specify this kind of numbers and perform calculations with them; see the math module for details.) Which type of matrix is created by the curly braces depends on the element types. Homogeneous matrices which contain only int, double or complex values yield the corresponding type of GSL matrix. Matrices can also hold any other type of Pure value or an arbitrary mix of values, in which case they become symbolic matrices; we’ll discuss these later.

The functions imatrix, dmatrix and cmatrix can be used to convert between the different kinds of numeric matrices. For instance:

```plaintext
> dmatrix {1,2,3;4,5,6};
{1.0,2.0,3.0;4.0,5.0,6.0}
> imatrix ans;
{1,2,3;4,5,6}
> cmatrix ans;
{1.0+:0.0,2.0+:0.0,3.0+:0.0;4.0+:0.0,5.0+:0.0,6.0+:0.0}
> dmatrix ans;
{1.0,0.0,2.0,0.0,3.0,0.0;4.0,0.0,5.0,0.0,6.0,0.0}
```

(Note that the latter conversion turns a complex into a double matrix, interleaving the real and imaginary parts of the original matrix.)

The same functions can also be used to construct zero matrices with given dimensions:

```plaintext
> imatrix (2,3);
{0,0,0;0,0,0}
> dmatrix (2,2);
{0.0,0.0;0.0,0.0}
> cmatrix (1,1);
{0.0+:0.0}
```

As already mentioned, this also gives you a direct way to create empty matrices with different dimensions. For instance:
The prelude offers matrix versions of the common list operations like `map`, `foldl`, `zip` etc., which provide a way to implement common matrix operations. E.g., multiplying a matrix `x` with a scalar `a` amounts to mapping the function `(a*)` to `x`, which can be done as follows:

```pure
> type scalar x = ~matrixp x;
> a::scalar * x::matrix = map (a*) x;
> 2*(1,2,3;4,5,6);
{2,4,6;8,10,12}
```

Note that the `matrix` type tag or the `matrixp` predicate can be used to restrict a variable to matrix values. (The prelude provides a few other types and corresponding predicates for various specific kinds of matrices, see the Pure Library Manual for details.) In addition, we also introduced a convenience type `scalar` for non-matrix values here, so that we can distinguish scalar from matrix multiplication which will be discussed below.

Matrix addition and other element-wise operations can be realized using `zipwith`, which combines corresponding elements of two matrices using a given binary function:

```pure
> x::matrix + y::matrix = zipwith (+) x y if dim x == dim y;
> {1,2,3;4,5,6}+{1,2,1;3,2,3};
{2,4,4;7,7,9}
```

Another way to define matrix functions in Pure is to employ a matrix pattern. The Pure language has built-in support for these, so that they work like the other kinds of patterns we’ve already encountered. For instance, to compute the dot product of two 2D vectors, you may write something like:

```pure
> {x1,y1}*{x2,y2} = x1*x2+y1*y2;
> {2,3}*{1,4};
14
```

Or, to compute the determinant of a 2x2 matrix:

```pure
> det {a,b;c,d} = a*d-b*c;
> det {1,2;3,4};
-2
```

These patterns are convenient if the dimensions of the involved matrices are small and known beforehand. If this isn’t the case then it’s better to use matrix comprehensions instead, which work with arbitrary dimensions and make it easy to express many simple kinds of algorithms which would typically be done using for loops in conventional programming languages.

Matrix comprehensions work pretty much like list comprehensions, but with a special twist: if values are drawn from lists then the generator clauses alternate between row and column generation. (More precisely, the last generator, which varies most quickly, yields a row, the next-to-last one a column of these row vectors, and so on.) This makes matrix comprehensions resemble customary mathematical notation very closely. For instance, here is how we
can define an operation to create a square identity matrix of a given dimension (note that the 
\(i==j\) term is just a Pure idiom for the Kronecker symbol):

\[
\text{eye } n = \{i==j \mid i = 1..n; j = 1..n\};
\]

\[
\text{eye } 3;
\]

\[
\{1,0,0;0,1,0;0,0,1\}
\]

Of course, matrix comprehensions can also draw values from other matrices instead of lists. In 
this case the block layout of the component matrices is preserved. For instance:

\[
\{x,y \mid x = \{1,2\}; y = \{a,b;c,d\}\};
\]

\[
\{(1,a),(1,b),(2,a),(2,b);(1,c),(1,d),(2,c),(2,d)\}
\]

Note that a matrix comprehension involving filters may fail because the filtered re-
sult isn’t a rectangular matrix any more. E.g., \(\{2*x\mid x=\{1,2,3,-4\}; x>0\}\) works, as does 
\(\{2*x\mid x=\{1,2,3,-4\}; x>0\}\), but \(\{2*x\mid x=\{1,2,3,-4\}; x>0\}\) doesn’t because the rows of the 
result matrix have different lengths.

As a slightly more comprehensive example (no pun intended!), here is a definition of matrix 
multiplication in Pure:

\[
x::\text{matrix} \ast y::\text{matrix} = \{\text{dot } u \ast v \mid u = \text{rows } x; v = \text{cols } y\}\text{ with}
\]

\[
\text{dot } u \ast v = \text{foldl } (+) 0 \$ \text{zipwith } (*) u (\text{rowvector } v);
\]

\[
\text{end if } m==n\text{ when } _,m = \text{dim } x; n,\_ = \text{dim } y\text{ end};
\]

The basic building block in this example is the dot product of two vectors, which is defined 
as a local function. The matrix product is obtained by simply calculating the dot product of 
all the rows of \(x\) with all the columns of \(y\). To make this work, the rows of \(x\) should be the 
same length as the columns of \(y\), we check this condition in the guard of the rule. Let’s give 
it a try:

\[
> \{1,0;0,1\} \ast \{1,2;3,4\};
\]

\[
\{1,2;3,4\}
\]

\[
> \{0,1;1,0\} \ast \{1,2;3,4\};
\]

\[
\{3,4;1,2\}
\]

\[
> \{0,1;1,0;1,1\} \ast \{1,2,3;4,5,6\};
\]

\[
\{4,5,6;1,2,3;5,7,9\}
\]

\[
> \{1,2;3,4\} \ast \{1;1\};
\]

\[
\{3;7\}
\]

Well, that was easy. So let’s take a look at a more challenging example, Gaussian elimination, 
which can be used to solve systems of linear equations. The algorithm brings a matrix into 
“row echelon” form, a generalization of triangular matrices. The resulting system can then 
be solved quite easily using back substitution.

Here is a Pure implementation of the algorithm. Note that the real meat is in the pivoting 
and elimination step (\text{step} function) which is iterated over all columns of the input matrix. 
In each step, \(x\) is the current matrix, \(i\) the current row index, \(j\) the current column index, and 
\(p\) keeps track of the current permutation of the row indices performed during pivoting. The 
algorithm returns the updated matrix \(x\), row index \(i\) and row permutation \(p\).
gauss_elimination x::matrix = p,x
when n,m = dim x; p,_,x = foldl step (0..n-1,0,x) (0..m-1) end;

// One pivoting and elimination step in column j of the matrix:
step (p,i,x) j = if max_x==0 then p,i,x
else
  // updated row permutation and index:
  transp i max_i p, i+1,
  {// the top rows of the matrix remain unchanged:}
  x!!(0..i-1,0..m-1);
  // the pivot row, divided by the pivot element:
  {x!(i,l)/x!(i,j) | l=0..m-1};
  // subtract suitable multiples of the pivot row:
  {x!(k,l)-x!(k,j)*x!(i,l)/x!(i,j) | k=i+1..n-1; l=0..m-1}
when
n,m = dim x; max_i, max_x = pivot i (col x j);
x = if max_x>0 then swap x i max_i else x;
end with
pivot i x = foldl max (0,0) [j,abs (x!j)|j=i..#x-1];
max (i,x) (j,y) = if x<y then j,y else i,x;
end;

Please refer to any good textbook on numerical mathematics for a closer description of the algorithm. But here is a brief rundown of what happens in each elimination step: First we find the pivot element in column \( j \) of the matrix. (We’re doing partial pivoting here, i.e., we only look for the element with the largest absolute value in column \( j \), starting at row \( i \). That’s usually good enough to achieve numerical stability.) If the pivot is zero then we’re done (the rest of the pivot column is already zeroed out). Otherwise, we bring it into the pivot position (swapping row \( i \) and the pivot row), divide the pivot row by the pivot, and subtract suitable multiples of the pivot row to eliminate the elements of the pivot column in all subsequent rows. Finally we update \( i \) and \( p \) accordingly and return the result.

In order to complete the implementation, we still need the following little helper functions to swap two rows of a matrix (this is used in the pivoting step) and to apply a transposition to a permutation (represented as a list):

swap x i j = x!!(transp i j (0..n-1),0..m-1) when n,m = dim x end;
transp i j p = [p!tr k | k=0..#p-1] with tr k = if k==i then j else if k==j then i else k end;

Finally, let us define a convenient print representation of double matrices a la Octave (the meaning of the \_\_show\_\_ function is explained in Pretty-Printing):

using system;
__show__ x::matrix
= strcat [printd j (x!(i,j))|i=0..n-1; j=0..m-1] + "\n" with printd 0 = sprintf "\%10.5f"; printd _ = sprintf "%10.5f" end
when n,m = dim x end if dmatrixp x;

Example:
> let x = dmatrix {2,1,-1,8; -3,-1,2,-11; -2,1,2,-3};
> x; gauss_elimination x;
 2.00000 1.00000 -1.00000 8.00000
-3.00000 -1.00000 2.00000 -11.00000
-2.00000 1.00000 2.00000 -3.00000
[1,2,0],
 1.00000 0.33333 -0.66667 3.66667
0.00000 1.00000 0.40000 2.60000
0.00000 0.00000 1.00000 -1.00000

1.5.15 Symbolic Matrices

As already mentioned, matrices may contain not just numbers but any kind of Pure values, in which case they become symbolic matrices. For instance:

> {1,2.0,3L; a,b,c};
{1,2.0,3L; a,b,c}

The smatrixp predicate gives you a quick way to check whether a matrix is a symbolic one:

> smatrixp ans;
1

Note that this may not always be obvious. For instance, you can use the smatrix function to explicitly convert a numeric matrix:

> smatrix {1,2;3,4};
{1,2;3,4}

This still looks the same as the original matrix, but smatrixp reveals that it's in fact a symbolic matrix:

> smatrixp ans;
1

Also note that the empty matrix is by default a symbolic matrix, as are matrices containing bigints:

> smatrixp {}; 1
> smatrixp {1L,2L;3L,4L}; 1

However, you can easily convert these to a numeric type if needed, e.g.:

> dmatrix {1L,2L;3L,4L};
{1.0,2.0;3.0,4.0}

Symbolic matrices are a convenient data structure for storing arbitrary collections of values which provides fast random access to its members. In particular, they can also be nested, and thus multidimensional tensors or arrays of arbitrary dimension can be realized as nested symbolic vectors. However, you have to be careful when constructing such values, because the {...} construct normally combines submatrices to larger matrices. For instance:
> {{1,2},{3,4}};
{1,2,3,4}

One way to inhibit this splicing of the submatrices in a larger matrix is to use the quote operator (cf. The Quote):

> '{{1,2},{3,4}};
{{1,2},{3,4}}

Note that this result is really different from {1,2;3,4}. The latter is a 2x2 integer matrix, while the former is a symbolic vector a.k.a. 1x2 matrix whose elements happen to be two integer vectors. So a double index will be required to access the subvector elements:

> ans!0!1;
2

You can also match these values with a nested matrix pattern, e.g.:

> let {{a,b},{c,d}} = '{{1,2},{3,4}};
> a,b,c,d;
1,2,3,4

Unfortunately, the quote operator in fact inhibits evaluation of all embedded subterms which may be undesirable if the matrix expression contains arithmetic (as in '{{1+1,2*3}}), so this method works best for constant matrices. A more general way to create a symbolic vector of matrices is provided by the vector function from the prelude, which is applied to a list of the vector elements as follows:

> vector {{1,2},{3,4}};
{{1,2},{3,4}}

Calls to the vector function can be nested to an arbitrary depth to obtain higher-dimensional “arrays”:

> vector [vector {{1,2}},vector {{3,4}}];
{{{1,2}},{3,4}}

This obviously becomes a bit unwieldy for higher dimensions, but Pure 0.56 and later provide the following shorthand notation:

> {{|{1,2},{3,4}|}};
{{|{1,2}|},{|{3,4}|}}

> {{|{|{1,2}|}|},{{|{3,4}|}|}};
{{{|{1,2}|}|},{|{3,4}|}}

This makes it much more convenient to denote nested vector values. Note that the {| |} construct doesn’t use any special magic, it’s just a standard outfix operator implemented as a Pure macro. For more details please check the description of the non-splicing vector brackets in the Pure Library Manual.
1.5.16 Record Data

Symbolic matrices also provide a means to represent simple record-like data, by encoding records as symbolic vectors consisting of “hash pairs” of the form key => value. This kind of data structure is very convenient to represent aggregates with lots of different components. Since the components of records can be accessed by indexing with key values, you don’t have to remember which components are stored in which order; just knowing the keys of the required members is enough. In contrast, tuples, lists and other kinds of constructor terms quickly become unwieldy for such purposes.

The keys used for indexing the record data must be either symbols or strings, while the corresponding values may be arbitrary Pure values. The prelude provides some operations on these special kinds of matrices, which let you retrieve vector elements by indexing and perform non-destructive updates, see the Record Functions section in the Pure Library Manual for details. Here are a few examples which illustrate how to create records and work with them:

> let r = {x=>5, y=>12};
> recordp r, member r x;
 1,1
> r!y; r!![y,x];
 12
{12,5}
> insert r (x=>99);
{x=>99,y=>12}
> insert ans (z=>77);
{x=>99,y=>12,z=>77}
> delete ans z;
{x=>99,y=>12}

Records can also be nested:

> let r = {a => {b=>1,c=>2}, b => 2};
> r!a, r!b, r!a!b;
{b=>1,c=>2},2,1

Note the use of the “hash rocket” => which denotes the key=>value associations in a record. The hash rocket is a constructor declared as an infix operator in the prelude, see the Hash Pairs section in the Pure Library Manual for details. There’s one caveat here, however. Since neither ‘=>’ nor ‘!’ treat their key operand in a special way, you’ll have to take care that the key symbols do not evaluate to something else, as might be the case if they are bound to a global or local variable or parameterless function:

> let u = 99;
> {u=>u};
{99=>99}

In the case of global variables and function symbols, you might protect the symbol with a quote (see The Quote):
However, even the quote doesn’t save you from local variable substitution:

```lisp
> {'u=>u} when u = 99 end;
{99=>99}
```

In such cases you’ll either have to rename the local variable, or use the prelude function `val` to quote the symbol:

```lisp
> {val "u"=>u} when u = 99 end;
{99=>99}
```

It’s also possible to directly use strings as keys instead, which may actually be more convenient in some cases:

```lisp
> let r ={"x"=>5, "y"=>12};
> keys r; vals r;
{"x","y"}
{5,12}
> update r "y" (r!"y"+1);
{"x=>5,"y"=>13}
```

You can also mix strings and symbols as keys in the same record (but note that strings and symbols are always distinct, so y and "y" are really two different keys here):

```lisp
> insert r (y=>99);
{"x=>5,"y"=>12,y=>99}
```

As records are in fact just special kinds of matrices, the standard matrix operations can be used on record values as well. For instance, the matrix constructor provides an alternative way to quickly augment a record with a collection of new key=>value associations:

```lisp
> let r = {x=>5, y=>12};
> let r = {r, x=>7, z=>3}; r;
{x=>5,y=>12,x=>7,z=>3}
> r!x, r!z;
7,3
> delete r x;
{x=>5,y=>12,z=>3}
> ans!x;
5
```

As the example shows, this may produce duplicate keys, but these are handled gracefully; indexing and updates will always work with the last association for a given key in the record. If necessary, you can remove duplicate entries from a record as follows; this will only keep the last association for each key:
> record r;
{x=>7,y=>12,z=>3}

In fact, the `record` operation not only removes duplicates, but also orders the record entries by keys. This produces a kind of normalized representation which is useful if you want to compare or combine two record values irrespective of the ordering of the fields. For instance:

> record {x=>5, y=>12} === record {y=>12, x=>5};
1

The `record` function can also be used to construct a normalized record directly from a list or tuple of hash pairs:

> record [x=>5, x=>7, y=>12];
{x=>7,y=>12}

Other matrix operations such as `map`, `foldl`, etc., and matrix comprehensions can be applied to records just as easily. This enables you to perform bulk updates of record data in a straightforward way. For instance, here's how you can define a function `maprec` which applies a function to all values stored in a record:

> maprec f = map (\(u=>v) -> u=>f v);
> maprec (*2) {x=>5,y=>12};
{x=>10,y=>24}

Another example: The following `ziprec` function collects pairs of values stored under common keys in two records (we also normalize the result here so that duplicate keys are always removed):

> ziprec x y = record {u=>(x!u,y!u) | u = keys x; member y u};
> ziprec {a=>3,x=>5,y=>12} {x=>10,y=>24,z=>7};
{x=>(5,10),y=>(12,24)}

Thus the full power of generic matrix operations is available for records, which turns them into a much more versatile data structure than records in conventional programming languages, which are usually limited to constructing records and accessing or modifying their components.

Note that since the values stored in records can be arbitrary Pure values, you can also have records with mutable components by making use of Pure's `expression references`. For instance:

> let r = {x=>ref 1,y=>ref 2}; maprec get r;
{x=>1,y=>2}
> put (r!x) 99; maprec get r;
99
{x=>99,y=>2}

Another interesting application of records are the “virtual method tables” used in object-oriented programming. Pure has a built-in `__locals__` macro which captures the environment of local functions at the point of the call and returns it as a list of hash pairs of function symbols and the corresponding closures. We can readily convert this into a record data structure which can be used as a virtual method table. For instance:
Here is a little helper macro that we can use to turn the virtual method table into an anonymous function which, when applied to a symbol, returns the appropriate closure:

```lisp
def obj = (\x -> vt!x) when
  vt = record __locals__;
end;
```

Continuing our example from Local Functions and Variables, we can now implement the point object as follows:

```lisp
point (x,y) = obj with
  coords () = get x,get y;
  move (dx,dy) = put x (get x+dx), put y (get y+dy);
end when
  x,y = ref x,ref y;
end;
```

Note that obj really needs to be implemented as a macro so that its body is inserted into the point function and the __locals__ call is executed in the context of the local function environment there. (A macro is like a function which gets evaluated at compile time; see the Macros section for details.) Also note that we changed the coords “method” so that it takes a dummy parameter () now; this prevents premature evaluation of the closure. If coords was a parameterless function then its value would be fixed at the time we construct the virtual method table, which is not what we want here.

Now we can write:

```lisp>
let p = point (1,2);
> p coords ()
(1,2)
> p move (2,3)
(3,5)
> p coords ()
(3,5)
```

This provides us with an interesting way to represent stateful objects which works very much like object-oriented programming. What’s still missing here is the inheritance of methods from other objects, but this can now be done by just combining virtual method tables using the record operations we’ve already discussed above; we leave this as an exercise for the interested reader.

## 1.5.17 The Quote

We’ve already seen some uses of the quote in previous examples, so let’s have a closer look at it now. As described in Special Forms, the quote operation quotes an expression, so that
it can be passed around and manipulated freely until its value is needed, in which case you can pass it to the `eval` function to obtain its value. For instance:

```plaintext
> let x = '(2*42+2^12); x;
  2*42+2^12
> eval x;
  4180.0
```

Lisp programmers will be well familiar with this operation which enables some powerful metaprogramming techniques. However, there are some notable differences to Lisp’s `quote`. In particular, `quote` only inhibits the evaluation of global variables, `local` variables are substituted as usual:

```plaintext
> (\x -> '(2*x+1)) 99;
  2*99+1
> foo x = '(2*x+1);
> foo 99; foo $ '(7/y);
  2*99+1
  2*(7/y)+1
> '(x+1) when x = '(2+3) end;
  2+3+1
> '(2*42+2^n) when n = 12 end;
  2*42+2^12
```

Local parameterless functions are treated in the same fashion:

```plaintext
> '(2*42+2^n) with n = 12 end;
  2*42+2^12
```

Note that, in contrast, for global variables (and functions) we have:

```plaintext
> let n = 12;
> '(2*42+2^n);
  2*42+2^n
```

This discrepancy may come as a surprise (or even annoyance) to real Lisp weenies, but it does have its advantages. As illustrated in the examples above, local variable substitution makes it easy to fill in the variable parts in a quoted “template” expression, without any need for an arguably complex tool like Lisp’s “quasiquote”. (But note that it is quite easy to define the quasiquote in Pure if you want it. See the Recursive Macros section for a simplified version; a full implementation can be found in the Pure library.)

If you do need to quote a symbol which is already being used as a local variable or function in the current context, you can do this by supplying the symbol as a string to the prelude function `val`:

```plaintext
> val "x"+x when x = 99 end;
  x+99
```

Also note that while local functions are always substituted in a quoted expression, applications involving local functions can still be quoted:
The quote also inhibits evaluation inside matrix expressions, including the “splicing” of embedded submatrices:

```
> '{1,2+3,2+3};
{1,2+3,2+3}
> '{1,{2,3},4};
{1,{2,3},4}
```

Special expressions (conditionals, lambda and the case, when and with constructs) can be quoted as well. But since these constructs cannot be directly represented at runtime, the quote actually produces some ordinary “placeholder” terms for these:

```
> '(x+1 when x = '(2*3) end);
  x+1 __when__ [x-->'(2*3)]
> eval ans;
  2*3+1
> '(2*42+(f 6 with f n = 2^(2*n) end));
  2*42+(f 6 __with__ [f n-->2^(2*n)])
> eval ans;
  4180.0
```

Note that these placeholders are in fact special built-in macros which reconstruct the special expression when evaluated. Moreover, special expressions are implicitly quoted when they occur on the left-hand side of an equation or as an argument of a “quoteargs” macro call. This is often used to implement macros which manipulate these constructs as literals. For instance, the following macro swaps the arguments in a lambda:

```
> #! --quoteargs bar
> def bar (\x y -> z) = __eval__ ('\y x -> z));
> show bar
  def bar (__lambda__ [x,y] z) = __eval__ ('__lambda__ [y,x] z));
> baz = bar (\a b -> a-b);
> show baz
  baz = \b a -> a-b;
> baz 2 3;
  1
```

The Macros section explains in detail how this meta programming works.

### 1.6 Declarations

Pure is a very terse language by design. Usually you don’t declare much stuff, you just define it and be done with it. However, there are a few constructs which let you declare symbols with special attributes and manage programs consisting of several source modules:

- symbol declarations determine “scope” and “fixity” of a symbol;
• **interface** declarations specify abstract data types;
• **extern** declarations specify external C functions;
• **using** clauses let you include other scripts in a Pure script;
• **namespace** declarations let you avoid name clashes and thereby make it easier to manage large programs consisting of many separate modules.

These are toplevel elements (cf. Toplevel):

```
item ::= symbol_decl | interface_decl | extern_decl
      | using_decl | namespace_decl
```

We defer the discussion of **extern** declarations to the C Interface section. The other kinds of declarations are described in the following subsections.

### 1.6.1 Symbol Declarations

Symbol declarations declare special attributes of a symbol, such as their scope (whether they are “public” or “private”) and their fixity (for operator symbols). The syntax of these declarations is as follows:

```
symbol_decl ::= scope qualified_symbol+ ";
               | [scope] fixity qualified_symbol+ ";
scope ::= "public" | "private"
fixity ::= "nonfix" | "outfix"
         | ("infix"|"infixl"|"infixr"|"prefix"|"postfix") precedence
precedence ::= integer | "(" op ")"
```

Scope declarations take the following form:

- `public symbol ...;`
- `private symbol ...;`

This declares the listed symbols as public or private, respectively. Each symbol must either be an identifier or a sequence of punctuation characters. The latter kind of symbols must always be declared before use, whereas ordinary identifiers can be used without a prior declaration in which case they are declared implicitly and default to public scope, meaning that they are visible everywhere in a program. An explicit public declaration of ordinary identifiers is thus rarely needed (unless you want to declare symbols as members of a specific namespace, see Namespaces below). Symbols can also be declared private, meaning that the symbol is visible only in the namespace it belongs to. This is explained in more detail under Private Symbols in the Namespaces section below.

**Note:** The declared symbols may optionally be qualified with a namespace prefix, but since new symbols can only be created in the current namespace, the namespace prefix must match the current namespace (see Namespaces). Thus the namespace prefix isn’t really needed, unless you want to declare a symbol which happens to be a reserved Pure keyword.
Pure Language and Library Documentation, Release 0.68

(cf. Lexical Matters). In this specific case, it will be necessary to use a qualified name so that the symbol isn’t mistaken for a keyword.

Note that to declare several symbols in a single declaration, you can list them all with white-space in between. The same syntax applies to the other types of symbol declarations discussed below. (Commas are not allowed as delimiters here, as they may occur as legal symbol constituents in the list of symbols.) The public and private keywords can also be used as a prefix in any of the special symbol declarations discussed below, to specify the scope of the declared symbols (if the scope prefix is omitted, it defaults to public).

The following “fixity” declarations are available for introducing special operator symbols. This changes the way that these symbols are parsed and thus provides you with a limited means to extend the Pure language at the lexical and syntactical level.

```
infix level symbol ...;
infixl level symbol ...;
infixr level symbol ...;
prefix level symbol ...;
postfix level symbol ...;
```

Pure provides you with a theoretically unlimited number of different precedence levels for user-defined infix, prefix and postfix operators. Precedence levels are numbered starting at 0; larger numbers indicate higher precedence. (For practical reasons, the current implementation does require that precedence numbers can be encoded as 24 bit unsigned machine integers, giving you a range from 0 to 16777215, but this should be large enough to incur no real limitations on applications. Also, the operator declarations in the prelude have been set up to leave enough “space” between the “standard” levels so that you can easily sneak in new operator symbols at low, high or intermediate precedences.)

On each precedence level, you can declare (in order of increasing precedence) infix (binary non-associative), infixl (binary left-associative), infixr (binary right-associative), prefix (unary prefix) and postfix (unary postfix) operators. For instance, here is a typical excerpt from the prelude (the full table can be found in the Prelude section of the Pure Library Manual):

```
infix 1800 < > <= >= == ~= ;
infixl 2200 + - ;
infixr 2300 * / div mod ;
infixr 2500 ^ ;
 prefix 2600 # ;
```

Note: Unary minus plays a special role in the syntax. Like in Haskell and following mathematical tradition, unary minus is the only prefix operator symbol which is also used as an infix operator, and is always on the same precedence level as binary minus, whose precedence may be chosen freely in the prelude. (The minus operator is the only symbol which gets that special treatment; all other operators must have distinct lexical representations.) Thus, with the standard prelude, -x+y will be parsed as (-x)+y, whereas -x*y is the same as -(x*y). Also note that the notation (-) always denotes the binary minus operator; the unary minus operation can be denoted using the built-in neg function.
Instead of denoting the precedence by an explicit integer value, you can also specify an existing operator symbol enclosed in parentheses. Thus the following declaration gives the ++ operator the same precedence as +:

```plaintext
infixl (+) ++ ;
```

The given symbol may be of a different fixity than the declaration, but it must have a proper precedence level (i.e., it must be an infix, prefix or postfix symbol). E.g., the following declaration gives ^^ the same precedence level as the infix ^ symbol, but turns it into a postfix operator:

```plaintext
postfix (^) ^^ ;
```

Pure also provides unary outfix operators, which work like in Wm Leler’s constraint programming language Bertrand. These can be declared as follows:

```plaintext
outfix left right ...;
```

Outfix operators let you define your own bracket structures. The operators must be given as pairs of matching left and right symbols (which must be distinct). For instance:

```plaintext
outfix | : : | BEGIN END;
```

After this declaration you can write bracketed expressions like | : x : | or BEGIN foo, bar END. These are always at the highest precedence level (i.e., syntactically they work like parenthesized expressions). Just like other operators, you can turn outfix symbols into ordinary functions by enclosing them in parentheses, but you have to specify the symbols in matching pairs, such as (BEGIN END).

Pure also has a notation for “nullary” operators, that is, “operators without operands”. These are used to denote special literals which simply stand for themselves. They are introduced using a `nonfix` declaration:

```plaintext
nonfix symbol ...;
```

For instance:

```plaintext
nonfix red green blue;
```

Semantically, nonfix symbols are a kind of “symbolic constants”. However, it is important to note the difference to `defined` constants, which are symbols bound to a constant value by means of a `const` definition. In fact, there are some use cases where a symbol may be both a defined constant and a nonfix symbol, see `Constant Definitions` in the `Caveats and Notes` section for details.

Syntactically, nonfix symbols work just like ordinary identifiers, so they may stand wherever an identifier is allowed (no parentheses are required to “escape” them). However, just like other kinds of operators, they may also consist of punctuation (which isn’t allowed in ordinary identifiers). The other difference to ordinary identifiers is that nonfix symbols are always interpreted as literals, even if they occur in a variable position on the left-hand side of a rule. So, with the above declaration, you can write something like:
foo x = case x of red = green; green = blue; blue = red end;
map foo [red,green,blue];
[green,blue,red]

Thus nonfix symbols are pretty much like nullary constructor symbols in languages like Haskell. Non-fixity is just a syntactic attribute, however. Pure doesn’t enforce that such values are irreducible, so you can still write a “constructor equation” like the following:

dec = blue;
map foo [red,green,blue];
[blue,blue,blue]

Examples for all types of symbol declarations can be found in the prelude which declares a bunch of standard (arithmetic, relational, logical) operator symbols as well as the list and pair constructors ‘:’ and ‘,’ and a few nonfix symbols (true and false, as well as different kinds of exceptions).

1.6.2 Interface Types

Besides the “concrete” types already described in the Type Rules section, Pure provides another, more abstract way to characterize a type through the collection of operations it supports. These interface types work pretty much like in Google’s Go programming language. They provide a safe form of Duck typing in which the operations available on a type are stated explicitly, and hence members of the type are always known to provide all of the listed operations.

An interface declaration gives the type name along with a collection of patterns, the so-called signature which specifies the manifest operations of the type:

```
interface_decl ::=  "interface" qualified_identifier
uplicates interface_item* "end" ";"
interface_item ::=  pattern ";"
                             | "interface" qualified_identifier ";"
```

Interfaces thus consist of two kinds of items:

- The patterns, which indicate which operations are supported by the type, and which arguments they expect. This may be anything that can occur as the left-hand side of an ordinary function definition, cf. General Rules.

- The name of another interface type. This causes the signature of the named interface type to be included in the interface type being defined, which effectively turns the new interface type into a subtype of the existing one.

The gist of an interface is in its patterns, more precisely: in the pattern variables which have the name of the interface as a type tag. The precise meaning of the patterns is as follows:

- The patterns are matched against the left-hand sides of ordinary function definitions. If a left-hand side matches, any argument pattern substituted for a variable tagged with the interface type becomes a “candidate pattern” of the type.
The type consists of all candidate patterns which can be matched by some candidate pattern of each interface function. That is, candidate patterns which are only supported by some but not all of the interface functions, are eliminated.

Finally, all trivial candidate patterns (x where x is just a variable without any type tag, which thus matches any value) are eliminated as well.

Interface patterns often take a simple form like the following,

```plaintext
interface foo with foo x::foo y z; end;
```

specifying the number of arguments of the interface function along with the position of the interface type argument. However, general patterns are permitted, in order to further restrict the left-hand sides of the function definitions to be taken into consideration. Specifically, note that type tags other than the interface type must always be matched literally on the left-hand sides of equations. Thus,

```plaintext
interface foo with foo x::foo y::int; end;
```

matches any rule of the form

```plaintext
foo x y::int = ...;
```

but not:

```plaintext
foo x \theta = ...;
foo x y::bar = ...;
```

(unless bar happens to be an alias of the int type, of course). In such cases it is necessary to explicitly add these patterns to the interface if you want them to be included.

Interface patterns may contain the interface type tag any number of times, yielding candidate patterns for each occurrence of the interface type tag in the pattern. For instance, here is a quick way to determine the type of all “addable” data structures in the prelude (this uses the interactive `show interface` command to list the patterns actually matched by an interface type, cf. The show Command):

```plaintext
> interface addable with x::addable + y::addable; end;
> show interface addable

type addable x::int;
type addable x::double;
type addable x::bigint;
type addable s::string;
type addable [];
type addable xs@(_:_);
```

On the other hand, interfaces may also contain “static” patterns which do not include the interface type as a tag at all, such as:

```plaintext
interface foo with bar x::bar y; end;
```

These do not contribute anything to the candidate patterns of the type, but do restrict the type just like the other patterns, in that the type will be empty unless the static patterns are...
all “implemented”. In the example above, this means that the foo type will be empty unless the bar function is defined and takes an element of the bar type as its first argument.

An interface may also be empty, in which case it matches any value. Thus,

```plaintext
interface any with end;
```

is just a fancy way to define the type:

```plaintext
type any _;
```

Interfaces can be composed in a piecemeal fashion, by adding more interface patterns. Thus,

```plaintext
interface foo with foo x::foo; end;
interface foo with bar x::foo; end;
```

is equivalent to:

```plaintext
interface foo with foo x::foo; bar x::foo; end;
```

It is also possible to include one interface in another, which effectively establishes a subtype relationship. For instance, here’s yet another way to define the foo interface above:

```plaintext
interface bar with
  bar x::bar;
end;

interface foo with
  foo x::foo;
  interface bar;
end;
```

This has the effect of including the signature of bar in foo (while renaming the interface type tags in the bar signature accordingly):

```plaintext
> show foo
interface foo with
  foo x::foo;
  bar x::foo;
end;
```

**Note:** Including interfaces is a static operation. Only the interface patterns known at the point of inclusion become part of the including interface; refining the included interface later has no effect on the set of included patterns. In particular, this also prevents circular interface definitions.

When composing interfaces in this fashion, it is easy to end up with duplicate interface patterns from various sources. The compiler removes such duplicates, even if they only match up to the renaming of variables. For instance:

```plaintext
> show bar foo
interface bar with
  bar x::bar;
```
Also note that, despite the obvious similarities between interfaces and classes in object-oriented programming, they are really different things. The former are essentially just signatures of functions living elsewhere, whereas the latter also include data layouts and method implementations. More on the similarities and differences of interfaces and classes can be found in the Go FAQ.

Let’s now take a look at the example of a stack data structure to see how this all works in practice:

```go
interface stack with
    push s::stack x;
    pop s::stack;
    top s::stack;
end;
```

Note the use of the type tag `stack` in the operation patterns, which marks the positions of `stack` arguments of the interface operations. The interface tells us that a stack provides three operations `push`, `pop` and `top` which each take a stack as their first argument; also, `push` takes two arguments, while `pop` and `top` just take a single (stack) argument.

This information is all that the compiler needs to figure out which terms are members of the `stack` data type. To these ends, the compiler looks at existing definitions of `push`, `pop` and `top` and extracts the patterns for arguments marked with the `stack` tag in the interface. The stack patterns implemented by all of the interface operations make up the `stack` type; i.e., the members of the type are all the instances of these patterns.

Right now our `stack` type doesn’t have any members, because we didn’t implement the interface operations yet, so let’s do this now. For instance, to implement stacks as lists, we might define:

```go
push xs[] x | push xs@(_:_) x = x:xs;
pop (x:xs) = xs;
top (x:xs) = x;
```

This is also known as “instantiating” the type. In addition, we will need an operation to create an initial stack value. The following will do for our purposes:

```go
1.6.2 Interface Types
stack xs::list = xs;

This yields a stack with the given initial contents. Let’s give it a go:

> top (push (stack []) 99);
99

Looks good so far. We can also check the actual definition of the type in terms of its `type` rules using the `show interface` command:

> show interface stack
type stack xs@(_:_);

Wait, something seems to be wrong there. The empty list pattern of the `push` function is missing, where did it go? Let’s restart the interpreter with warnings enabled (`-w`) and retype the above definitions. The compiler then tells us:

> show interface stack
warning: interface 'stack' may be incomplete
warning: function 'push' might lack a rule for 'xs@[]'
warning: function 'top' might lack a rule for 'xs@[]'
type stack xs@(_:_);

See? A pattern is only considered part of the type if it is supported by all the interface operations. Since the `pop` and `top` operations don’t have any rules for empty list arguments, empty lists are excluded from the type. We can fix this quite easily by adding the following “error rules” which handle this case:

> pop [] = throw "empty stack";
> top [] = throw "empty stack";
> show interface stack
type stack xs@[];
type stack xs@(_:_);

This looks fine now, so let’s see how we can put our new stack data structure to good use. Operations on the type are defined as usual, employing `stack` as a type tag for stack arguments so that we can be sure that the `push`, `pop` and `top` operations are all supported. For instance, let’s implement a little RPN (“Reverse Polish Notation”) calculator:

```
if nargs op<=#ys;
= call (top xs:ys) (pop xs) op otherwise;

end;
```

This takes an initial stack `xs` and a list `ops` of operands and operations as inputs and returns the resulting stack after processing `ops`. Examples:

> rpn (stack []) [10,4,3,(+),2,(*),(-)];
[-4]
> using math;
> rpn (stack []) [1,2,ln,(/)];
[1.44269504088896]
rpn (stack []) [4,1,atan,(*)];
[3.14159265358979]
rpn (stack []) [2,(*)];
<stdin>, line 5: unhandled exception "empty stack" while evaluating
'rpn (stack []) [2,(*)]'

Ok, this is all very nice, but it seems that so far we haven’t done much more than we could have achieved just as easily with plain lists instead. So what are the benefits of having an interface type?

First, an interface provides a fair amount of safety. As long as we stick to the interface functions, we can be sure that the data is capable of carrying out the requested operations. At the same time, the interface also serves as a valuable piece of documentation, since it tells us at a glance exactly which operations are supported by the type.

Second, an interface provides data abstraction. We don’t need to know how the interface operations are implemented, and in fact functions coded against the interface will work with any implementation of the interface. For instance, suppose that we’d like to provide a “bounded stacks” data structure, i.e., stacks which don’t grow beyond a certain limit. These can be implemented as follows:

```pure
push (n,xs::{}) x | push (n,xs@(_:_)) x =
    if n>0 then (n-1,x:xs) else throw "full stack";
pop (n,x:xs) = n+1,xs;
top (n,x:xs) = x;
pop (n,[]) = throw "empty stack";
top (n,[]) = throw "empty stack";
```

Note that we represent a bounded stack by a pair \((n, xs)\) here, where \(xs\) is the list of elements and \(n\) is the “free space” (number of elements we still allow to be pushed). We also add a function to construct such values:

```pure
bstack n::int xs::list = (n-#xs,xs);
```

Without any further ado, our little RPN calculator works just fine with the new variation of the data structure:

```pure
> rpn (bstack 3 []) [10,4,3,(+),2,(*)]; 2,[-4]
> rpn (bstack 2 []) [10,4,3,(+),2,(*)];
<stdin>, line 7: unhandled exception "full stack" while evaluating
'rpn (bstack 2 []) [10,4,3,(+),2,(*)]'
```

While they’re quite useful in general, Pure’s interface types also have their limitations. In particular, the guarantees provided by an interface are of a purely syntactic nature; the signature doesn’t tell us anything about the actual meaning of the provided operations, so unit testing is still needed to ensure certain semantic properties of the implementation. Some further issues due to Pure’s dynamically typed nature are discussed under Interfaces in the Caveats and Notes section.
1.6.3 Modules and Imports

Pure doesn’t offer separate compilation, but the following type of declaration provides a simple but effective way to assemble a Pure program from several source modules.

\[
\text{using}\_\text{decl} \ ::= \ "\text{using}\ name\ (","\ name\)*\ ";"
\]

\[
\text{name} \ ::= \ \text{qualified}\_\text{identifier} | \text{string}
\]

The \text{using} declaration takes the following form (note that in contrast to symbol declarations, the comma is used as a delimiter symbol here):

\[
\text{using}\ name,\ ...;
\]

This causes each given script to be included in the Pure program at the given point (if it wasn’t already included before), which makes available all the definitions of the included script in your program. Note that each included script is loaded only \textit{once}, when the first \text{using} clause for the script is encountered. Nested imports are allowed, i.e., an imported module may itself import other modules, etc. A Pure program then basically is the concatenation of all the source modules given as command line arguments, with other modules listed in \text{using} clauses inserted at the corresponding source locations.

(The \text{using} clause also has an alternative form which allows dynamic libraries and LLVM bitcode modules to be loaded, this will be discussed in the C Interface section.)

For instance, the following declaration causes the math.pure script from the standard library to be included in your program:

\[
\text{using}\ math;
\]

You can also import multiple scripts in one go:

\[
\text{using}\ array,\ \text{dict},\ \text{set};
\]

Moreover, Pure provides a notation for qualified module names which can be used to denote scripts located in specific package directories, e.g.:

\[
\text{using}\ \text{examples::libor::bits};
\]

In fact this is equivalent to the following \text{using} clause which spells out the real filename of the script between double quotes (the \text{.pure} suffix can also be omitted in which case it is added automatically):

\[
\text{using}\ \text{"examples/libor/bits.pure"};
\]

Both notations can be used interchangeably; the former is usually more convenient, but the latter allows you to denote scripts whose names aren’t valid Pure identifiers.

Script identifiers are translated to the corresponding filenames by replacing the ‘::’ symbol with the pathname separator ‘/’ and tacking on the ‘.pure’ suffix. The following table illustrates this with a few examples.
Note the last example, which shows how an absolute pathname can be denoted using a qualifier starting with ‘::’.

Unless an absolute pathname is given, the interpreter performs a search to locate the script. The search algorithm considers the following directories in the given order:

- the directory of the current script, which is the directory of the script containing the using clause, or the current working directory if the clause was read from standard input (as is the case, e.g., in an interactive session);
- the directories named in -I options on the command line (in the given order);
- the colon-separated list of directories in the PURE_INCLUDE environment variable (in the given order);
- finally the directory named by the PURELIB environment variable.

Note that the current working directory is not searched by default (unless the using clause is read from standard input), but of course you can force this by adding the option -I to the command line, or by including ‘.’ in the PURE_INCLUDE variable.

The directory of the current script (the first item above) can be skipped by specifying the script to be loaded as a filename in double quotes, prefixed with the special sys: tag. The search then starts with the “system” directories (-I, PURE_INCLUDE and PURELIB) instead. This is useful, e.g., if you want to provide your own custom version of a standard library script which in turn imports that library script. For instance, a custom version of math.pure might employ the following using clause to load the math.pure script from the Pure library:

using "sys:math";
// custom definitions go here
log2 x = ln x/ln 2;

The interpreter compares script names (to determine whether two scripts are actually the same) by using the canonicalized full pathname of the script, following symbolic links to the destination file (albeit only one level). Thus different scripts with the same basename, such as foo/utils.pure and bar/utils.pure can both be included in the same program (unless they link to the same file).

More precisely, canonicalizing a pathname involves the following steps:

- relative pathnames are expanded to absolute ones, using the search rules discussed above;
- the directory part of the pathname is normalized to the form returned by the getcwd system call;
- the ”.pure” suffix is added if needed;

1.6.3 Modules and Imports 135
• if the resulting script name is actually a symbolic link, the interpreter follows that link to its destination, albeit only one level. (This is only done on Unix-like systems.)

The directory of the canonicalized pathname is also used when searching other scripts included in a script. This makes it possible to have an executable script with a shebang line in its own directory, which is then executed via a symbolic link placed on the system PATH.

In this case the script search performed in using clauses will use the real script directory and thus other required scripts can be located there. This is the recommended practice for installing standalone Pure applications in source form which are to be run directly from the shell.

1.6.4 Namespaces

To facilitate modular development, Pure also provides namespaces as a means to avoid name clashes between symbols, and to keep the global namespace tidy and clean. Namespaces serve as containers holding groups of related identifiers and other symbols. Inside each namespace, symbols must be unique, but the same symbol may be used to denote different objects (variables, functions, etc.) in different namespaces. (Pure’s namespace system was heavily inspired by C++ and works in a very similar fashion. So if you know C++ you should feel right at home and skimming this section to pick up Pure’s syntax of the namespace constructs should be enough to start using it.)

The global namespace is always available. By default, new symbols are created in this namespace, which is also called the default namespace. Additional namespaces can be created with the namespace declaration, which also switches to the given namespace (makes it the current namespace), so that new symbols are then created in that namespace rather than the default one. The current namespace also applies to all kinds of symbol declarations, including operator and nonfix symbol declarations, as well as extern declarations (the latter are described in the C Interface section).

The syntax of namespace declarations is captured by the following grammar rules:

```
namespace_decl ::= "namespace" [name] [brackets] ";"  
                 | "namespace" name [brackets] "with" item+ "end" ";"  
                 | "using" "namespace" [name_spec ("," name_spec)*] ";"  

brackets ::= "(" left_op right_op ")"  
name_spec ::= name ["(" qualified_symbol+ ")]"
```

The basic form of the namespace declaration looks as follows (there’s also a “scoped” form of the namespace declaration which will be discussed in Scoped Namespaces at the end of this section):

```
namespace name;  
// declarations and definitions in namespace ‘name’  
namespace;  
```

The second form switches back to the default namespace. For instance, in order to define two symbols with the same print name foo in two different namespaces foo and bar, you can write:
namespace foo;
foo x = x+1;
namespace bar;
foo x = x-1;
namespace;

We can now refer to the symbols we just defined using qualified symbols of the form namespace::symbol:

> foo::foo 99;
100
> bar::foo 99;
98

This avoids any potential name clashes, since the qualified identifier notation always makes it clear which namespace the given identifier belongs to.

A namespace can be “reopened” at any time to add new symbols and definitions to it. This allows namespaces to be created that span several source modules. You can also create several different namespaces in the same module.

Similar to the using declaration, a namespace declaration accepts either identifiers or double-quoted strings as namespace names. E.g., the following two declarations are equivalent:

namespace foo;
namespace "foo";

The latter form also allows more descriptive labels which aren't identifiers, e.g.:

namespace "Private stuff, keep out!";

Note that the namespace prefix in a qualified identifier must be a legal identifier, so it isn’t possible to access symbols in namespaces with such descriptive labels in a direct fashion. The only way to get at the symbols in this case is with namespace brackets or by using a namespace or using namespace declaration (for the latter see Using Namespaces below).

Using Namespaces

Since it is rather inconvenient if you always have to write identifiers in their qualified form outside of their “home” namespace, Pure allows you to specify a list of search namespaces which are used to look up symbols not in the default or the current namespace. This is done with the using namespace declaration, which takes the following form:

using namespace name1, name2, ...;
// ...
using namespace;

As with namespace declarations, the second form without any namespace arguments gets you back to the default empty list of search namespaces.

For instance, consider this example:
namespace foo;

foo x = x+1;

namespace bar;

bar x = x+1;

namespace;

The symbols in these namespaces can be accessed unqualified as follows:

> using namespace foo;
> foo 99;
100
> using namespace bar;
> foo 99;
98
> bar 99;
100

This method is often to be preferred over opening a namespace with the namespace declaration, since using namespace only gives you “read access” to the imported symbols, so you can’t accidentally mess up the definitions of the namespace you’re using. Another advantage is that the using namespace declaration also lets you search multiple namespaces at once:

using namespace foo, bar;

Be warned, however, that this brings up the very same issue of name clashes again:

> using namespace foo, bar;
> foo 99;
<stdin>, line 15: symbol ‘foo’ is ambiguous here

In such a case you’ll have to resort to using namespace qualifiers again, in order to resolve the name clash:

> foo::foo 99;
100

To avoid this kind of mishap, you can also selectively import just a few symbols from a namespace instead. This can be done with a declaration of the following form:

using namespace name1 ( sym1 sym2 ... ), name2 ... ;

As indicated, the symbols to be imported can optionally be placed as a whitespace-delimited list inside parentheses, following the corresponding namespace name. (As with symbol declarations, the symbols may optionally be qualified with a namespace prefix, which must match the imported namespace here.) For instance:

> using namespace foo, bar (bar);
> foo 99;
100
> bar 99;
Note that now we have no clash on the foo symbol any more, because we restricted the import from the bar namespace to the bar symbol, so that bar::foo has to be denoted with a qualified symbol now.

Symbol Lookup and Creation

Pure’s rules for looking up and creating symbols are fairly straightforward and akin to those in other languages featuring namespaces. However, there are some intricacies involved, because the rewriting rule format of definitions allows “referential” use of symbols not only in the “body” (right-hand side) of a definition, but also in the left-hand side patterns. We discuss this in detail below.

The compiler searches for symbols first in the current namespace (if any), then in the currently active search namespaces (if any), and finally in the default (i.e., the global) namespace, in that order. This automatic lookup can be bypassed by using an absolute namespace qualifier of the form ::foo::bar. In particular, ::bar always denotes the symbol bar in the default namespace, while ::foo::bar denotes the symbol bar in the foo namespace. (Normally, the latter kind of notation is only needed if you have to deal with nested namespaces, see Hierarchical Namespaces below.)

If no existing symbol is found, a new symbol is created automatically, by implicitly declaring a public symbol with default attributes. New unqualified symbols are always created in the current namespace, while new qualified symbols are created in the namespace given by the namespace prefix of the symbol.

Note: Pure’s implicit symbol declarations are a mixed blessing. They are convenient, especially in interactive usage, but they also let missing or mistyped symbols go unnoticed much too easily. As a remedy, in the case of qualified symbols the compiler checks that the given namespace prefix matches the current namespace, in order to catch typos and other silly mistakes and prevent you from accidentally clobbering the contents of other namespaces. For instance:

```
> namespace foo;
> namespace;
> foo::bar x = 1/x;
<stdin>, line 3: undeclared symbol ‘foo::bar’
```

To make these errors go away it’s enough to just declare the symbols in their proper namespaces.

In addition, you can run the interpreter with the -w option (see Invoking Pure) to check your scripts for (non-defining) uses of undeclared unqualified function symbols. This is highly recommended. For instance, in the following example we forgot to import the system module which defines the puts function. Running the interpreter with -w highlights such potential errors:
$ pure -w
> puts "bla"; // missing import of system module
<stdin>, line 1: warning: implicit declaration of 'puts'
puts "bla"

For legitimate uses (such as forward uses of a symbol which is defined later), you can make these warnings go away by declaring the symbol before using it.

New symbols are also created if a global unqualified (and yet undeclared) symbol is being “defined” in a rewriting rule or let/const definition, even if a symbol with the same print name from another namespace is already visible in the current scope. To distinguish “defining” from “referring” uses of a global symbol, Pure uses the following (purely syntactic) notions:

- A **defining occurrence** of a global function, macro or type symbol is any occurrence of the symbol as the (leftmost) head symbol on the left-hand side of a rewriting rule.
- A **defining occurrence** of a global variable or constant symbol is any occurrence of the symbol in a variable position (as given by the “head = function” rule, cf. Variables in Equations) on the left-hand side of a let or const definition.
- All other occurrences of global symbols on the left-hand side, as well as all symbol occurrences on the right-hand side of a definition are **referring occurrences**. (Note that this also subsumes all occurrences of type tags on the left-hand side of an equation.)

The following example illustrates these notions:

```plaintext
namespace foo;
bar (bar x) = bar x;
let x,y = 1,2;
namespace;
```

Here, the first occurrence of bar on the left-hand side bar (bar x) of the first rule is a defining occurrence, as are the occurrences of x and y on the left-hand side of the let definition. Hence these symbols are created as new symbols in the namespace foo. On the other hand, the other occurrences of bar in the first rule, as well as the ‘,’ symbol on the left-hand side of the let definition are referring occurrences. In the former case, bar refers to the bar symbol defined by the rule, while in the latter case the ‘,’ operator is actually declared in the prelude and thus imported from the global namespace.

The same rules of lookup also apply to type tags on the left-hand side of an equation, but in this case the interpreter will look specifically for type symbols, avoiding any other kinds of symbols which might be visible in the same context. Thus, in the following example, the type tag bar is correctly resolved to bar::bar, even though the (function) symbol foo::bar is visible at this point:

```plaintext
> namespace bar;
> type bar;
> namespace foo;
> public bar;
> using namespace bar;
```
Note that special operator (and nonfix) symbols always require an explicit declaration. This works as already discussed in the Symbol Declarations section, except that you first switch to the appropriate namespace before declaring the symbols. For instance, here is how you can create a new + operation which multiplies its operands rather than adding them:

```plaintext
> namespace my;
> infixl 2200 +;
> x+y = x*y;
> 5+7;
35
```

Note that the new + operation really belongs to the namespace we created. The + operation in the default namespace works as before, and in fact you can use qualified symbols to pick the version that you need:

```plaintext
> namespace;
> 5+7;
12
> 5 my:+ 7;
12
> 5 my::+ 7;
35
```

Here’s what you get if you happen to forget the declaration of the + operator:

```plaintext
> namespace my;
> x+y = x*y;
<stdin>, line 2: infixl symbol '+' was not declared in this namespace
```

Thus the compiler will never create a new instance of an operator symbol on the fly, an explicit declaration is always needed in such cases.

Note that if you really wanted to redefine the global + operator, you can do this even while the my namespace is current. You just have to use a qualified identifier in this case, as follows:

```plaintext
> namespace my;
> x ::+ y = x*y;
> a+b;
a*b
```

This should rarely be necessary (in the above example you might just as well enter this rule while in the global namespace), but it can be useful in some circumstances. Specifically, you might want to “overload” a global function or operator with a definition that makes use of private symbols of a namespace (which are only visible inside that namespace; see Private Symbols below). For instance:
> x ::+ y = bar x y;
> a+b;
a*b

(The above is a rather contrived example, since the very same functionality can be accomplished much easier, but there are some situations where this method is needed.)

Private Symbols

Pure also allows you to have private symbols, as a means to hide away internal operations which shouldn’t be accessed directly outside the namespace in which they are declared. The scope of a private symbol is confined to its namespace, i.e., the symbol is only visible when its “home” namespace is current. Symbols are declared private by using the `private` keyword in the symbol declaration:

```> namespace secret;
> private baz;
> // 'baz' is a private symbol in namespace 'secret' here
> baz x = 2*x;
> // you can use 'baz' just like any other symbol here
> baz 99;
198
> namespace;
```

Note that, at this point, `secret::baz` is now invisible, even if you have `secret` in the search namespace list:

```> using namespace secret;
> // this actually creates a 'baz' symbol in the default namespace:
> baz 99;
baz 99
> secret::baz 99;
<stdin>, line 27: symbol 'secret::baz' is private here
```

The only way to bring the symbol back into scope is to make the `secret` namespace current again:

```> namespace secret;
> baz 99;
198
> secret::baz 99;
198
```

Namespace Brackets

All the namespace-related constructs we discussed so far only provide a means to switch namespaces on a per-rule basis. Sometimes it is convenient if you can switch namespaces on the fly inside an expression. This is especially useful if you want to embed a domain-specific sublanguage (DSL) in Pure. DSLs typically provide their own system of operators which differ from the standard Pure operators and thus need to be declared in their own namespace.
To make this possible, Pure allows you to associate a namespace with a corresponding pair of outfix symbols. This turns the outfix symbols into special namespace brackets which can then be used to quickly switch namespaces in an expression by just enclosing a subexpression in the namespace brackets.

To these ends, the syntax of namespace declarations allows you to optionally specify a pair of outfix symbols inside parentheses after the namespace name. The outfix symbols to be used as namespace brackets must have been declared beforehand. For instance:

```pure
outfix " »;
namespace foo (« »);
infixr (::^) ^;
x^y = 2*x+y;
namespace;
```

The code above introduces a foo namespace which defines a special variation of the (^) operator. It also associates the namespace with the « » brackets so that you can write:

```
> (a+b)^c+10;
(a+b)^c+10
> «(a+b)^c»+10;
2*(a+b)+c+10
```

Note the use of the namespace brackets in the second input line. This changes the meaning of the ^ operator, which now refers to foo::^ instead. Also note that the namespace brackets themselves are removed from the resulting expression; they are only used to temporarily switch the namespace to foo inside the bracketed subexpression. This works pretty much like a namespace declaration (so any active search namespaces remain in effect), but is limited in scope to the bracketed subexpression and only gives access to the public symbols of the namespace (like a using namespace declaration would do).

The rules of visibility for the namespace bracket symbols themselves are the same as for any other symbols. So they need to be in scope if you want to denote them in unqualified form (which is always the case if they are declared in the default namespace, as in the example above). If necessary, you can also specify them in their qualified form as usual.

Namespace brackets can be used anywhere inside an expression, even on the left-hand side of a rule. So, for instance, we might also have written the example above as follows:

```pure
outfix « »;
namespace foo (« »);
infixr (::^) ^;
namespace;

«x^y» = 2*x+y;
```

Note the use of the namespace brackets on the last line. This rule actually expands to:

```
x foo::^ y = 2*x+y;
```

The special meaning of namespace brackets can be turned off and back on again at any time with a corresponding namespace declaration. For instance:
> namespace (« »); // turn off the special meaning of « »
> «(a+b)^c+10;
> (a+b)^c+10
> namespace foo (« »); // turn it on again
> namespace;
> «(a+b)^c+10;
> 2*(a+b)+c+10

(Note that as a side effect these declarations also change the current namespace, so that we use the namespace; declaration in the second last line to change back to the default namespace.)

As shown in the first line of the example above, a namespace brackets declaration without a namespace just turns off the special processing of the brackets. In order to define a namespace bracket for the default namespace, you need to explicitly specify an empty namespace instead, as follows:

> outfix « : : »;
> namespace " (« : »);
> «(a+b)^«:x^y:»»;
> 2*(a+b)+x^y

As this example illustrates, namespace brackets can also be nested, which is useful, e.g., if you need to combine subexpressions from several DSLs in a single expression. In this example we employ the «:x^y:» subexpression to temporarily switch back to the default namespace inside the « »-bracketed expression which is parsed in the foo namespace.

Hierarchical Namespaces

Namespace identifiers can themselves be qualified identifiers in Pure, which enables you to introduce a hierarchy of namespaces. This is useful, e.g., to group related namespaces together under a common “umbrella” namespace:

```plaintext
namespace my;
namespace my::old;
foo x = x+1;
namespace my::new;
foo x = x-1;
```

Note that the namespace my, which serves as the parent namespace, must be created before the my::old and my::new namespaces, even if it does not contain any symbols of its own. After these declarations, the my::old and my::new namespaces are part of the my namespace and will be considered in name lookup accordingly, so that you can write:

```plaintext>
using namespace my;
old::foo 99;
100
new::foo 99;
98
```

This works pretty much like a hierarchy of directories and files, where the namespaces play
the role of the directories (with the default namespace as the root directory), the symbols in each namespace correspond to the files in a directory, and the \texttt{using namespace} declaration functions similar to the shell’s \texttt{PATH} variable.

Sometimes it is necessary to tell the compiler to use a symbol in a specific namespace, bypassing the usual symbol lookup mechanism. For instance, suppose that we introduce another \texttt{global old} namespace and define yet another version of \texttt{foo} in that namespace:

\begin{verbatim}
namespace old;
foo x = 2*x;
namespace;
\end{verbatim}

Now, if we want to access that function, with \texttt{my} still active as the search namespace, we cannot simply refer to the new function as \texttt{old::foo}, since this name will resolve to \texttt{my::old::foo} instead. As a remedy, the compiler accepts an \texttt{absolute} qualified identifier of the form \texttt{::old::foo}. This bypasses name lookup and thus always yields exactly the symbol in the given namespace (if it exists; as mentioned previously, the compiler will complain about an undeclared symbol otherwise):

\begin{verbatim}
> old::foo 99;
100
> ::old::foo 99;
198
\end{verbatim}

Also note that, as a special case of the absolute qualifier notation, \texttt{::foo} always denotes the symbol \texttt{foo} in the default namespace.

**Scoped Namespaces**

Pure also provides an alternative scoped \texttt{namespace} construct which makes nested namespace definitions more convenient. This construct takes the following form:

\begin{verbatim}
namespace name with ... end;
\end{verbatim}

The part between \texttt{with} and \texttt{end} may contain arbitrary declarations and definitions, using the same syntax as the toplevel. These are processed in the context of the given namespace, as if you had written:

\begin{verbatim}
namespace name;
...
namespace;
\end{verbatim}

However, the scoped namespace construct always returns you to the namespace which was active before, and thus these declarations may be nested:

\begin{verbatim}
namespace foo with
  // declarations and definitions in namespace foo
namespace bar with
  // declarations and definitions in namespace bar
end;
// more declarations and definitions in namespace foo
end;
\end{verbatim}
Note that this kind of nesting does not necessarily imply a namespace hierarchy as discussed in Hierarchical Namespaces. However, you can achieve this by using the appropriate qualified namespace names:

```plaintext
global_namespace foo
    with
        // ...
    namespace foo::bar
        with
            // ...
    end
    // ...
end
```

Another special feature of the scoped namespace construct is that using namespace declarations are always local to the current namespace scope (and other nested namespace scopes inside it). Thus the previous setting is restored at the end of each scope:

```plaintext
using namespace foo;
namespace foo
    with
        // still using namespace foo here
using namespace bar;
namespace bar
    with
        // still using namespace bar here
using namespace foo;
end;
// back to using namespace bar
end;
// back to using namespace foo at toplevel
```

Finally, here’s a more concrete example which shows how scoped namespaces might be used to declare two namespaces and populate them with various functions and operators:

```plaintext
namespace foo
    with
        infixr (::^) ^;
        foo x = x+1;
        bar x = x-1;
        x^y = 2*x+y;
    end

namespace bar
    with
        outfix <: :>;  
        foo x = x+2;
        bar x = x-2;
    end

using namespace foo(^ foo), bar(bar <: :>);
// namespace foo
foo x;
  x^y;
```
```plaintext
// namespace bar
bar x;
<: x,y :>;
```

Pure’s namespaces can thus be used pretty much like “packages” or “modules” in languages like Ada or Modula-2. They provide a structured way to describe program components offering collections of related data and operations, which can be brought into scope in a controlled way by making judicious use of `using namespace` declarations. They also provide an abstraction barrier, since internal operations and data structures can be hidden away employing private symbols.

Please note that these facilities are not Pure’s main focus and thus they are somewhat limited compared to programming languages specifically designed for big projects and large teams of developers. Nevertheless they should be useful if your programs grow beyond a small collection of simple source modules, and enable you to manage most Pure projects with ease.

## 1.7 Macros

Macros are a special type of functions to be executed as a kind of “preprocessing stage” at compile time. In Pure these are typically used to define custom special forms and to perform inlining of function calls and other kinds of source-level optimizations.

Whereas the macro facilities of most programming languages simply provide a kind of textual substitution mechanism, Pure macros operate on symbolic expressions and are implemented by the same kind of rewriting rules that are also used to define ordinary functions in Pure. This makes them robust and easy to use for most common preprocessing purposes.

Syntactically, a macro definition looks just like a function definition with the `def` keyword in front of it. Only unconditional rewriting rules are permitted here, i.e., rules without guards and multiple right-hand sides. However, multiple left-hand sides can be employed as usual to abbreviate a collection of rules with the same left-hand side, as described in the General Rules section.

The major difference between function and macro definitions is that the latter are processed at compile time rather than run time. To these ends, macro calls on the right-hand sides of function, constant and variable definitions are evaluated by reducing them to normal form using the available macro rules. The resulting expressions are then substituted for the macro calls. All macro substitution happens before constant substitutions and the actual compilation step. Macros can be defined in terms of other macros (also recursively), and are normally evaluated using call by value (i.e., macro calls in macro arguments are expanded before the macro gets applied to its parameters).

In the first half of this section we start out with some common uses of macros which should cover most aspects of macro programming that the average Pure programmer will need. The remainder of this section then discusses some more advanced features of Pure’s macro system intended for power users.
1.7.1 Optimization Rules

Let’s begin with a simple example of an optimization rule from the prelude, which eliminates saturated instances of the right-associative function application operator (you can find this near the beginning of prelude.pure):

```pure
def f $ x = f x;
```

Like in Haskell, ‘$’ in fact just denotes function application, but it is a low-priority operator which is handy to write cascading function calls. With the above macro rule, these will be “inlined” as ordinary function applications automatically. Example:

```pure
> foo x = bar $ bar $ 2*x;
> show foo
foo x = bar (bar (2*x));
```

Note that a macro may have the same name as an ordinary Pure function, which is essential if you want to inline calls to an existing function. (Just like ordinary functions, the number of parameters in each rule for a given macro must be the same, but a macro may have a different number of arguments than the corresponding function.)

When running interactively, you can follow the reduction steps the compiler performs during macro evaluation. To these ends, you have to set “tracepoints” on the relevant macros, using the `trace` command with the `-m` option; see Interactive Commands. (This works even if the interpreter is run in non-debugging mode.) Note that since macro expansion is performed at compile time, you’ll have to do this before entering the definitions in which the macro is used. However, in many cases you can also just enter the right-hand side of the equation at the interpreter prompt to see how it gets expanded. For instance:

```pure
> trace -m $
> bar $ bar $ 2*x;
-- macro ($): bar$2*x --> bar (2*x)
-- macro ($): bar$bar (2*x) --> bar (bar (2*x))
bar (bar (2*x))
```

Now let’s see how we can add our own optimization rules. Suppose we’d like to expand saturated calls of the `succ` function. This function is defined in the prelude; it just adds 1 to its single argument. We can inline such calls as follows:

```pure
> def succ (x+y) = x+(y+1);
> def succ x = x+1;
> foo x = succ (succ (succ x));
> show foo
foo x = x+3;
```

Again, let’s see exactly what’s going on there:

```pure
> trace -m succ
> succ (succ (succ x));
-- macro succ: succ x --> x+1
-- macro succ: succ (x+1) --> x+(1+1)
```

---

1.7 Macros
Note that the contraction of the subterm 1+1+1 to the integer constant 3 is actually done by the compiler after macro expansion has been performed. This is also called “constant folding”, see Constant Definitions in the Caveats and Notes section for details. It is also the reason that we added the first rule for succ. This rule may seem superflous at first sight, but actually it is needed to massage the sum into a form which enables constant folding.

Rules like these can help the compiler generate better code. Of course, the above examples are still rather elementary. Pure macros can do much more elaborate optimizations, but for this we first need to discuss how to write recursive macros, as well as macros which take apart special terms like lambdas. After that we’ll return to the subject of optimization rules in Advanced Optimization below.

### 1.7.2 Recursive Macros

Macros can also be recursive, in which case they usually consist of multiple rules and make use of pattern-matching just like ordinary function definitions.

#### Note:
Pure macros are just as powerful as (unconditional) term rewriting systems and thus they are Turing-complete. This implies that a badly written macro may well send the Pure compiler into an infinite recursion, which results in a stack overflow at compile time.

As a simple example, let’s see how we can inline invocations of the `# size` operator on list constants:

```pure
def #[] = 0;
def #(x:xs) = #xs+1;
```

As you can see, the definition is pretty straightforward; exactly the same rules might also be used for an ordinary function definition, although the standard library actually implements `#` a bit differently to make good use of tail recursion. Let’s check that this actually works:

```pure
> foo = #[1,2,3,4];
> show foo
foo = 4;
```

Note that the result of macro expansion is actually 0+1+1+1+1 here, you can check that by running the macro with `trace -m #`. Constant folding contracts this to 4 after macro expansion, as explained in the previous subsection.

This was rather easy. So let’s implement a more elaborate example: a basic Pure version of Lisp’s quasiquote which allows you to create a quoted expression from a “template” while substituting variable parts of the template. (For the sake of brevity, we present a somewhat abridged version here which does not cover all corner cases. The full version of this macro can be found as lib/quasiquote.pure in the Pure distribution.)
def quasiquote (unquote x) = x;
def quasiquote (f@_ (splice x)) = foldl ($) (quasiquote f) x;
def quasiquote (f@_ x) = quasiquote f (quasiquote x);
def quasiquote x = quote x;

(Note the f@_, which is an anonymous “as” pattern forcing the compiler to recognize f as a function variable, rather than a literal function symbol. See “As” Patterns in the Caveats and Notes section for an explanation of this trick.)

The first rule above takes care of “unquoting” embedded subterms. The second rule “splices” an argument list into an enclosing function application. The third rule recurse into subterms of a function application, and the fourth and last rule takes care of quoting the “atomic” subterms. Note that unquote and splice themselves are just passive constructor symbols, the real work is done by quasiquote, using foldl at runtime to actually perform the splicing. (Putting off the splicing until runtime makes it possible to splice argument lists computed at runtime.)

If we want, we can also add some syntactic sugar for Lisp weenies. (Note that we cannot have ‘, for unquoting, so we use ,($) instead.)

prefix 9 ' ,($) ,@ ;
def 'x = quasiquote x; def ,x = unquote x; def ,@x = splice x;

Examples:
> '(2*42+2^12);
 2*42+2^12
> '(2*42+,($2^12));
 2*42+4096.0
> ‘foo 1 2 ,(0) 2/3,3/4 (5/6);
foo 1 2 (2/3) (3/4) (5/6)
> ‘foo 1 2 ,(args) 5/6 when args = ’[2/3,3/4] end;
foo 1 2 (2/3) (3/4) (5/6)

1.7.3 User-Defined Special Forms

The quasiquote macro in the preceding subsection also provides an example of how you can use macros to define your own special forms. This works because the actual evaluation of macro arguments is put off until runtime, and thus we can safely pass them to built-in special forms and other constructs which defer their evaluation at runtime. In fact, the right-hand side of a macro rule may be an arbitrary Pure expression involving conditional expressions, lambdas, binding clauses, etc. These are never evaluated during macro substitution, they just become part of the macro expansion (after substituting the macro parameters).

Here is another useful example of a user-defined special form, the macro timex which employs the system function clock to report the cpu time in seconds needed to evaluate a given expression, along with the computed result:

> using system;
> def timex x = (clock-t0)/CLOCKS_PER_SEC,y when t0 = clock; y = x end;
> sum = foldl (+) 0L;
> timex $ sum (1L..100000L);
0.43,5000050000L

Note that the above definition of `timex` wouldn’t work as an ordinary function definition, since by virtue of Pure’s basic eager evaluation strategy the \( x \) parameter would have been evaluated already before it is passed to `timex`, making `timex` always return a zero time value.

Try it!

### 1.7.4 Macro Hygiene

Pure macros are lexically scoped, i.e., the binding of symbols in the right-hand-side of a macro definition is determined statically by the text of the definition, and macro parameter substitution also takes into account binding constructs, such as `with` and `when` clauses, in the right-hand side of the definition. Macro facilities with these pleasant properties are also known as **hygienic macros**. They are not susceptible to so-called “name capture,” which makes macros in less sophisticated languages bug-ridden and hard to use.

Macro hygiene is a somewhat esoteric topic for most programmers, so let us take a brief look at what it’s all about. The problem avoided by hygienic macros is that of *name capture*. There are actually two kinds of name capture which may occur in unhygienic macro systems:

- A free symbol in the macro *body* inadvertently becomes bound to the value of a local symbol in the context in which the macro is called.
- A free symbol in the macro *call* inadvertently becomes bound to the value of a local symbol in the macro body.

Pure’s hygienic macros avoid both pitfalls. Here is an example for the first form of name capture:

```plaintext
> def G x = x+y;
> G 10 when y = 99 end;
10+y
```

Note that the expansion of the `G` macro correctly uses the global instance of `y`, even though `y` is locally defined in the context of the macro call. (In some languages this form of name capture is sometimes used deliberately in order to make the macro use the binding of the symbol which is active at the point of the macro call. Normally, this won’t work in Pure, although there is a way to force this behaviour in Pure as well, see Name Capture in the Caveats and Notes section.)

In contrast, the second form of name capture is usually not intended, and is therefore more dangerous. Consider the following example:

```plaintext
> def F x = x+y when y = x+1 end;
> F y;
y+(y+1)
```

Pure again gives the correct result here. You’d have to be worried if you got \((y+1)+(y+1)\) instead, which would result from the literal expansion `y+y when y = y+1 end`, where the
(free) variable $y$ passed to $F$ gets captured by the local binding of $y$. In fact, that’s exactly what you get with C macros:

```
#define F(x) { int y = x+1; return x+y; }
```

Here $F(y)$ expands to `{ int y = y+1; return y+y; }` which is usually not what you want.

This completes our little introduction to Pure’s macro facilities. The above material should in fact cover all the common uses of macros in Pure. However, if you want to become a real Pure macro wizard then read on. In the following subsections we’re going to discover some more advanced features of Pure’s macro system which let you write macros for manipulating special forms and give you access to Pure’s reflection capabilities.

### 1.7.5 Built-in Macros and Special Expressions

As already mentioned in The Quote, special expressions such as conditionals and lambdas cannot be directly represented as runtime data in Pure. But they can be quoted in which case they are replaced by corresponding “placeholder terms”. These placeholder terms are in fact implemented as built-in macros which, when evaluated, construct the corresponding specials.

**macro __ifelse__** $x$ $y$ $z$

This macro expands to the conditional expression `if $x$ then $y$ else $z$` during macro evaluation.

**macro __lambda__** $[x_1,...,x_n]$ $y$

Expands to the lambda expression `$\lambda x_1 \ldots x_n \rightarrow y$`.

**macro __case__** $x$ $[(x_1 \rightarrow y_1),\ldots,(x_n \rightarrow y_n)]$

Expands to the `case` expression `case $x$ of $x_1 = y_1; \ldots; x_n = y_n$ end`. Note that the `$\rightarrow$` symbol is used to separate the left-hand side and the right-hand side of each rule (see below).

**macro $x$ __when__ $[(x_1 \rightarrow y_1),\ldots,(x_n \rightarrow y_n)]$**

Expands to the `when` expression `when $x$ when $x_1 = y_1; \ldots; x_n = y_n$ end`. Here the left-hand side of a rule may be omitted if it is just the anonymous variable; i.e., `$x$ __when__ $[\langle foo \rightarrow y\rangle]$` is the same as `$x$ __when__ $[\langle \rightarrow foo \ y\rangle]$`.

**macro $x$ __with__ $[(x_1 \rightarrow y_1),\ldots,(x_n \rightarrow y_n)]$**

Expands to the `with` expression `with $x$ with $x_1 = y_1; \ldots; x_n = y_n$ end`.

Note that the following low-priority infix operators are used to denote equations in the __case__, __when__ and __with__ macros:

**constructor** $x \rightarrow y$

Denotes an equation $x = y$.

**constructor** $x$ __if__ $y$

Attaches a guard to the right-hand side of an equation. That is, `$x \rightarrow y$ __if__ $z$` denotes the conditional equation $x = y$ if $z$. This symbol is only recognized in __case__ and __with__ calls.
In addition, patterns on the left-hand side of equations or in lambda arguments may be decorated with the following constructor terms to indicate “as” patterns and type tags (these are infix operators with a very high priority):

**constructor** \( x \__\text{as}\__ y \)

Denotes an “as” pattern \( x \circ y \).

**constructor** \( x \__\text{type}\__ y \)

Denotes a type tag \( x :: y \).

Note that all these symbols are in fact just constructors which are only interpreted in the context of the built-in macros listed above; they aren’t macros themselves.

It’s good to remember the above when you’re doing macro programming. However, to see the placeholder term of a special, you can also just type a quoted expression in the interpreter:

\[
> '\text{\texttt{\textbackslash x->x+1}}';
\]

\[
\__\text{lambda}\__ [\text{x}] (x+1)
\]

\[
> '\text{\texttt{\textbackslash f with f x = y when y = x+1 end end}}';
\]

\[
f \__\text{with}\__ [f x --> y \__\text{when}\__ [y --> x+1]]
\]

List and matrix comprehensions can also be quoted. These are basically syntactic sugar for lambda applications, cf. Primary Expressions. The compiler expands them to their “unsugared” form already before macro substitution, so no special kinds of built-in macros are needed to represent them. When quoted, comprehensions are thus denoted in their unsugared form, which consists of a pile of lambda expressions and list or matrix construction functions for the generation clauses, and possibly some conditionals for the filter clauses of the comprehension. For instance:

\[
> '\text{\texttt{\textbackslash [2*x | x = 1..3]}}';
\]

\[
\text{listmap} (\__\text{lambda}\__ [x] (2*x)) (1..3)
\]

Here’s how type tags and “as” patterns in quoted specials look like:

\[
> '\text{\texttt{(\texttt{x::int}->x+1)}}';
\]

\[
\__\text{lambda}\__ [x \__\text{type}\__ \text{int}] (x+1)
\]

\[
> '\text{\texttt{(dup (1..3) with dup xs@(x:_)=x:xs end)}}';
\]

\[
dup (1..3) \__\text{with}\__ [dup (xs \__\text{as}\__ (x:_))-->x:xs]
\]

Note that the placeholder terms for the specials are quoted here, and hence they are not evaluated (quoting inhibits macro expansion, just like it prevents the evaluation of ordinary function calls). Evaluating the placeholder terms executes the corresponding specials:

\[
> '\text{\texttt{(dup (1..3) with dup xs@(x:_)=x:xs end)}}';
\]

\[
dup (1..3) \__\text{with}\__ [dup (xs \__\text{as}\__ (x:_))-->x:xs]
\]

\[
> \text{eval ans};
\]

\[
[1,1,2,3]
\]

Of course, you can also just enter the macros directly (without quoting) to have them evaluated:
The `__str__` function can be used to pretty-print quoted specials:

```pure
> __str__ ('__lambda__ [x __type__ int] (x+1));
"|\x::int -> x+1"
> __str__ ('(dup (1..3) __with__ [dup (xs __as__ (x:_))-->x:xs]));
"dup (1..3) with dup xs@(x:_)= x:xs end"
```

This is useful to see which expression a quoted special will expand to. Note that `__str__` can also be used to define print representations for quoted specials with `__show__` (described in Pretty-Printing) if you always want to have them printed that way by the interpreter.

As quoted specials are just ordinary Pure expressions, they can be manipulated by functions just like any other term. For instance, here’s how you can define a function which takes a quoted lambda and swaps its two arguments:

```pure
> swap (__lambda__ [x,y] z) = '(__lambda__ [y,x] z);
> swap ('(\a b->a-b));
__lambda__ [b,a] (a-b)
> eval ans 2 3; // same as (\b a->a-b) 2 3
1
```

For convenience, a literal special expression can also be used on the left-hand side of an equation, in which case it actually denotes the corresponding placeholder term. So the `swap` function can also be defined like this (note that we first scratch the previous definition of `swap` with the `clear` command, see Interactive Commands):

```pure
> clear swap
> swap (\x y -> z) = '(%y x -> z);
> swap ('(\a b->a-b));
__lambda__ [b,a] (a-b)
```

This is usually easier to write and improves readability. However, there are cases in which you want to work with the built-in macros in a direct fashion. In particular, this becomes necessary when writing more generic rules which deal, e.g., with lambdas involving a variable number of arguments, or if you need real (i.e., unquoted) type tags or “as” patterns in a placeholder pattern. We’ll see examples of these later.

Quoted specials can be manipulated with macros just as well as with functions. In fact, this is quite common and thus the macro evaluator has some special support to make this more convenient. Specifically, it is possible to make a macro quote its arguments in an automatic fashion, by means of the `--quoteargs` pragma. To illustrate this, let’s redefine `swap` as a macro:
The `--quoteargs` pragma makes the `swap` macro receive its argument unevaluated, as if it was quoted (but without a literal quote around it). Therefore the quote on the lambda argument of `swap` can now be omitted. However, the result is still a quoted lambda. It’s tempting to just omit the quote on the right-hand side of the macro definition as well, in order to get a real lambda instead:

```plaintext
> clear swap
> def swap (\x y -> z) = '(\y x -> z);
> swap (\a b->a-b);
\_lambda\_ [b,a] (a-b)
```

We got a closure all right, but apparently it’s not the right one. Let’s use `trace -m` to figure out what went wrong:

```plaintext
> trace -m swap
> swap (\a b->a-b);
-- macro swap: swap (\a b -> a-b) --> \y x -> a-b
#<closure 0x7f1934157248>
> ans 2 3;
```

```
We got a closure all right, but apparently it’s not the right one. Let’s use `trace -m` to figure out what went wrong:

> trace -m swap
> swap (\a b->a-b);
-- macro swap: swap (\a b -> a-b) --> \y x -> a-b
#<closure 0x7f1934157248>
> ans 2 3;
```

```
Ok, so the result is the lambda \(\ y \ x \ -> \ a\-b\), not \(\ b \ a \ -> \ a\-b\) as we expected. This happens because we used a literal (unquoted) lambda on the right-hand side, which does its own variable binding; consequently, the variables \(x\) and \(y\) are bound by the lambda in this context, not by the left-hand side of the macro rule.

So just putting an unquoted lambda on the right-hand side doesn’t do the job. One way to deal with the situation is to just employ the `\_lambda\_` macro in a direct way, as we’ve seen before:

```plaintext
> clear swap
> def swap (\_lambda\_ [x,y] z) = __lambda__ [y,x] z;
> swap (\a b->a-b);
-- macro swap: swap (\a b -> a-b) --> \_lambda\_ [b,a] (a-b)
-- macro __lambda__: __lambda__ [b,a] (a-b) --> \b a -> a-b
#<closure 0x7f1934156f00>
> ans 2 3;
```

```
This works, but doesn’t look very nice. Often it’s more convenient to first construct a quoted term involving the necessary specials and then have it evaluated during macro evaluation. Pure provides yet another built-in macro for this purpose:

```
macro __eval__ x
```

Evaluate \(x\) at macro expansion time. This works by stripping one level of (outermost)
quotes from x and performing macro expansion on the resulting unquoted subexpressions.

Using \texttt{\_\_eval\_}, we can implement the swap macro as follows:

\begin{verbatim}
> clear swap
> def swap (\x y -> z) = __eval__ ('(\y x -> z));
> swap (\a b -> a-b);  
-- macro swap: swap (\a b -> a-b) --> __eval__ ('__lambda__ [b,a] (a-b))
-- macro __lambda__: __lambda__ [b,a] (a-b) --> \b a -> a-b
-- macro __eval__: __eval__ ('__lambda__ [b,a] (a-b)) --> \b a -> a-b
#<closure 0x7f7e1f867dc8>
> ans 2 3;
1
\end{verbatim}

Lisp programmers should note the difference. In Lisp, macros usually yield a quoted expression which is evaluated implicitly during macro expansion. This is never done automatically in Pure, since many Pure macros work perfectly well without it. Instead, quotes in a macro expansion are treated as literals, and you’ll have to explicitly call \texttt{\_\_eval\_} to remove them during macro evaluation.

A final caveat: Placeholder terms for specials are just simple expressions; they don’t do any variable binding by themselves. Thus the rules of \texttt{macro hygiene} don’t apply to them, which makes it possible to manipulate lambdas and local definitions in any desired way. On the other hand, this means that it is the programmer’s responsibility to avoid accidental name capture when using these facilities. Most macro code will work all right when written in a straightforward way, but there are some corner cases which need special attention (cf. Name Capture).

Sometimes the only convenient way to avoid name capture is to create new symbols on the fly. This will often be necessary if a macro generates an entire block construct (\texttt{case}, \texttt{when}, \texttt{with} or \texttt{lambda}) from scratch. The following built-in macro is provided for this purpose:

\texttt{macro \_\_gensym\_}

Create a new unqualified symbol which is guaranteed to not exist at the time of the macro call. These symbols typically look like \texttt{\_x123\_} and can be used for any purpose (i.e., as global or local as well as function or variable symbols).

For instance, here’s how we can implement a macro \texttt{foo} which creates a lambda from a given argument, using \texttt{\_\_gensym\_} to generate a fresh local variable for the lambda argument. This guarantees that variables in the argument expression don’t get captured by the lambda variable when the closure is created with a call to the built-in \texttt{\_\_lambda\_} macro.

\begin{verbatim}
> def foo x = bar __gensym__ x;
> define bar x y = __lambda__ [x] (x+y);
> trace -m foo
> foo (a*b);
-- macro foo: foo (a*b) --> bar __gensym__ (a*b)
-- macro __gensym__: __gensym__ --> __x1__
-- macro bar: bar __x1__ (a*b) --> __lambda__ [__x1__] (__x1__+a*b)
-- macro __lambda__: __lambda__ [__x1__] (__x1__+a*b) --> \__x1__ -> __x1__+a*b
#<closure 0x7f66f6c88db0>
\end{verbatim}
The __gensym__ macro returns a new variable for each invocation, and always ensures that it doesn’t accidently reuse a symbol already introduced by the user (even if it looks like a symbol that __gensym__ might itself create):

```plaintext
> foo (a*__x2__);  -- macro foo: foo (a*__x2__) --> bar __gensym__ (a*__x2__)  -- macro __gensym__: __gensym__ --> __x3__  -- macro bar: bar __x3__ (a*__x2__) --> __lambda__ [__x3__] (__x3__+a*__x2__)  -- macro __lambda__: __lambda__ [__x3__] (__x3__+a*__x2__) --> __x3__+a*__x2__
```

1.7.6 Advanced Optimization

We are now in a position to have a look at some of the trickier optimization macros defined in the prelude. The following __do__ macro can be found near the end of the prelude.pure module; it is used to optimize the case of “throwaway” list and matrix comprehensions. This is useful if a comprehension is evaluated solely for its side effects. To keep things simple, we discuss a slightly abridged version of the __do__ macro which only deals with list comprehensions and ignores some obscure corner cases. You can find this version in the examples/do.pure script. Please also check the prelude for the full version of this macro.

Note that we define our own versions of void and __do__ here which are placed into the my namespace to avoid conflicts with the prelude.

```plaintext
namespace my;

void _ = ();

#! --quoteargs my::__do__

def void [x] = void x;
def void (catmap f x) | void (listmap f x) = __do__ f x;

// Recurse into embedded generator clauses.
def __do__ (__lambda__ [x] y@(listmap _ _)) |
  __do__ (__lambda__ [x] y@(catmap _ _)) =
  __do__ $ (__lambda__ [x] (void y));

// Recurse into embedded filter clauses.
def __do__ (__lambda__ [x] (__ifelse__ y z [])) =
  __do__ $ (__lambda__ [x] (__ifelse__ y (void z) ()));

// Eliminate extra calls to ‘void’ in generator clauses.
def __do__ (__lambda__ [x] (void y)) = __do__ (__lambda__ [x] y);

// Eliminate extra calls to ‘void’ in filter clauses.
```

1.7.6 Advanced Optimization
def __do__ (__lambda__ [x] (__ifelse__ y (void z) ())) =
__do__ (__lambda__ [x] (__ifelse__ y z ()));

// Any remaining instances reduce to a plain 'do' (this must come last).
def __do__ f = do f;

First, note that the void function simply throws away its argument and returns () instead. The do function applies a function to every member of a list (like \texttt{map}), but throws away all intermediate results and just returns (), which is much more efficient if you don’t need those results anyway. These are both defined in the prelude, but we define our own version of void here so that we can hook it up to our simplified version of the __do__ macro.

The __do__ macro eventually reduces to just a plain do call, but applies some optimizations along the way. While the above rules for __do__ are always valid optimizations for do, it’s a good idea to use a separate macro here instead of clobbering do itself, so that these optimizations do not interfere with calls to do in ordinary user code. The prelude handles this in an analogous fashion.

Before we further delve into this example, a few remarks are in order about the way list comprehensions are implemented in Pure. As already mentioned, list comprehensions are just syntactic sugar; the compiler immediately transforms them to an equivalent expression involving only lambdas and a few other list operations. The latter are essentially equivalent to piles of nested filters and maps, but for various reasons they are actually implemented using two special helper operations, \texttt{catmap} and \texttt{listmap}.

The \texttt{catmap} operation combines \texttt{map} and \texttt{cat}; this is needed, in particular, to accumulate the results of nested generators, such as \texttt{[i,j | i = 1..n; j = 1..m]}. The same operation is also used to implement filter clauses, you can see this below in the examples. However, for efficiency simple generators like \texttt{[2*i | i = 1..n]} are translated to a \texttt{listmap} instead (which is basically just \texttt{map}, but works with different aggregate types, so that list comprehensions can draw values from aggregates other than lists, such as matrices).

Now let’s see how the rules above transform a list comprehension if we “void” it. (Remember to switch to the \texttt{my} namespace when trying the following examples.)

```plaintext
> using system;
> using namespace my;
> f = [printf "%g\n" (2^x+1) | x=1..5; x mod 2];
> g = void [printf "%g\n" (2^x+1) | x=1..5; x mod 2];
> show f g
f = catmap \(x \rightarrow \text{if } x \bmod 2 \text{ then } \text{printf } "%g\n" (2^x+1) \text{ else } [] \) (1..5);
g = do \(x \rightarrow \text{if } x \bmod 2 \text{ then } \text{printf } "%g\n" (2^x+1) \text{ else } () \) (1..5);
```

As you can see, the \texttt{catmap} got replaced with a \texttt{do}, and the list brackets inside the lambda were eliminated as well. These optimizations are just what’s needed to make this code go essentially as fast as a for loop in traditional programming languages (up to constant factors, of course). Here’s how it looks like when we run the \texttt{g} function:

```plaintext
> g;
3
9
```

158 1.7 Macros
It’s also instructive to have a look at how the above macro rules work in concert to rewrite a “voided” comprehension. To these ends, you can rerun the right-hand side of \( g \) with some tracing enabled, as follows (we omit the tracing output here for brevity):

```plaintext
> trace -m my::void
> void [printf \"%g\n\" (2^x+1) | x=1..5; x mod 2];
```

The above optimization rules also take care of nested list comprehensions, since they recurse into the lambda bodies of generator and filter clauses. For instance:

```plaintext
> h = void [puts $ str (x,y) | x=1..2; y=1..3];
> show h
h = do (\x -> do (\y -> puts (str (x,y))) (1..3)) (1..2);
```

Again, you should run this with macro tracing enabled to see how the __do__ macro recurses into the outer lambda body of the list comprehension. Here’s the rule which actually does this:

```plaintext
def __do__ (__lambda__ [x] y@(catmap _ _)) =
    __do__ $ (__lambda__ [x] (void y));
```

Note that in order to make this work, __do__ is implemented as a “quoteargs” macro so that it can inspect and recurse into the lambda terms in its argument. Also note the $ on the right-hand side of this rule; this is also implemented as a macro in the prelude. Here the $ operator is used to forcibly evaluate the macro argument __lambda__ [x] (void y), so that the embedded call to the void macro gets expanded. (Without the $ the argument to __do__ would be quoted and thus not be evaluated.) A similar rule is used to recurse into embedded filter clauses, as in the example of the function \( g \) above.

It should be mentioned that, while our version of the __do__ macro will properly handle most list comprehensions, there is a rather obscure corner case which it still refuses to optimize: outermost filter clauses. For instance, consider:

```plaintext
> let c = 2;
> k = void [printf \"%g\n\" (2^x+1) | c>0; x=1..3];
> show k
k = my::void (if c>0 then listmap (\x -> printf \"%g\n\" (2^x+1)) (1..3) else []);
```

It’s possible to handle this case as well, but we have to go to some lengths to achieve that. The complication here is that we don’t want to mess with calls to void in ordinary user code, so void itself cannot be a “quoteargs” macro. But the quoted form of void’s argument is needed to detect the “outermost filter clause” situation. The interested reader may refer to the prelude code to see how the prelude implementation of __do__ uses some helper macros to make this work. Another detail of the full version of __do__ is the handling of patterns on the left-hand side of generator clauses, which requires some special magic to filter out unmatched list elements; we also omitted this here for brevity.

### 1.7.6 Advanced Optimization

159
1.7.7 Reflection

The meta representation of specials discussed in Built-in Macros and Special Expressions is also useful to obtain information about the running program and even modify it. Pure’s runtime provides some built-in operations to implement these reflection capabilities, which are comparable in scope to what the Lisp programming language offers.

Specifically, the `get_fundef` function allows you to retrieve the definition of a global Pure function. Given the symbol denoting the function, `get_fundef` returns the list of rewriting rules implementing the functions, using the same `lhs --> rhs` format used by the `__case__`, `__when__` and `__with__` macros discussed above. For instance:

```pure
> fact n = 1 if n<=1;
> = n*fact (n-1) otherwise;
> get_fundef fact;
[(fact n-->1 __if__ n<=1),(fact n-->n*fact (n-1))]
```

Defining a new function or extending an existing function definition can be done just as easily, using the `add_fundef` function:

```pure
> add_fundef "$ ['(fib n-->1 __if__ n<=1),(fib n-->fib (n-2)+fib (n-1))]; ()
> show fib
fib n = 1 if n<=1;
fib n = fib (n-2)+fib (n-1);
> map fib (0..10);
[1,1,2,3,5,8,13,21,34,55,89]
```

Note that, to be on the safe side, we quoted the rule list passed to `add_fundef` to prevent premature evaluation of symbols used in the rules. This is necessary because `add_fundef` is an ordinary function, not a macro. (Of course, you could easily define a macro which would take care of this, if you like. We leave this as an exercise to the reader.)

Also note that `add_fundef` doesn’t override existing function definitions. It simply keeps on adding rules to the current program, just as if you typed the equations at the command prompt of the interpreter. It is possible to delete individual equations with `del_fundef`:

```pure
> del_fundef "$ '(fib n-->fib (n-2)+fib (n-1)); ()
> show fib
fib n = 1 if n<=1;
```

Moreover, the `clearsym` function allows you to completely get rid of an existing function:

```pure
> clearsym fib 0;
()
> show fib
> fib 9;
fib 9
```

There’s also a companion function, `globsym`, which enables you to get a list of defined symbols which match a given glob pattern:
Note that `globsym` also returns symbols defined as types, macros, variables or constants. But we can easily check for a given type of symbol by using the appropriate function to retrieve the rules defining the symbol, and filter out symbols with an empty rule list:

```
> #[sym | sym = globsym "*" 0; ~null (get_fundef sym)];
```

Pure also provides the operations `get_typedef`, `get_macdef`, `get_vardef` and `get_constdef`, which are completely analogous to `get_fundef`, but return the definitions of types, macros, (global) variables and constants. Note that in the latter two cases the rule list takes the form `[var-->val]` if the symbol is defined, `[]` if it isn’t.

For instance, let’s check the definition of the `$` macro (cf. Optimization Rules) and the `list` type (cf. Recursive Types):

```
> get_macdef ($);
[f$x-->f x]
> get_typedef list;
[(list []--->1),(list (_:_)--->1)]
```

Or let’s lists all global variables along with their values:

```
> catmap get_vardef (globsym "*" 0);
[(argc-->0),(argv--->[]),(compiling-->0),
(sysinfo-->"x86_64-unknown-linux-gnu"),(version-->"0.68")]
```

The counterparts of `add_fundef` and `del_fundef` are provided as well. Not very surprisingly, they are named `add_typedef`, `del_typedef`, etc. For instance:

```
> add_vardef ['x-->3*33];
()
> show x
let x = 99;
> del_vardef ('x);
()
> show x
```

The above facilities should cover most metaprogramming needs. For even more exotic requirements, you can also use the `eval` and `evalcmd` primitives to execute arbitrary Pure code in text form; please see the Pure Library Manual for details.

Finally, a word of caution: The use of `add_fundef`, `del_fundef` and similar operations to modify a running program breaks referential transparency and hence these functions should be used with care. Moreover, at present the JIT compiler doesn’t support truly self-modifying code (i.e., functions modifying themselves while they’re executing); this results...
in undefined behaviour. Also, note that none of the inspection and mutation capabilities provided by these operations will work in batch-compiled programs, please check the Batch Compilation section for details.

### 1.8 Exception Handling

Pure also offers a useful exception handling facility. To raise an exception, you just invoke the built-in function `throw` with the value to be thrown as the argument. Exceptions are caught with the built-in special form `catch` which is invoked as follows:

```pure
catch handler x
    Catch an exception. The first argument denotes the exception handler (a function to be applied to the exception value). The second (call-by-name) argument is the expression to be evaluated.
```

For instance:

```pure
> catch error (throw hello_world);
error hello_world
```

Exceptions are also generated by the runtime system if the program runs out of stack space, when a guard does not evaluate to a truth value, and when the subject term fails to match the pattern in a pattern-matching lambda abstraction, or a `let`, `case` or `when` construct. These types of exceptions are reported using the symbols `stack_fault`, `failed_cond` and `failed_match`, respectively, which are declared as nonfix symbols in the standard prelude. You can use `catch` to handle these kinds of exceptions just like any other. For instance:

```pure
> fact n = if n>0 then n*fact(n-1) else 1;
> catch error (fact foo);
error failed_cond
> catch error (fact 1000000);
error stack_fault
```

Unhandled exceptions are reported by the interpreter with a corresponding error message:

```pure
> fact foo;
<stdin>, line 2: unhandled exception ‘failed_cond’ while evaluating ‘fact foo’
```

Note that since the right-hand side of a type definition (cf. Type Rules) is just ordinary Pure code, it may be susceptible to exceptions, too. Such exceptions are reported or caught just like any other. In particular, if you want to make a type definition just fail silently in case of an exception, you’ll have to wrap it up in a suitable `catch` clause:

```pure
> foo x = throw foo; // dummy predicate which always throws an exception
> type bar x = foo x;
> type baz x = catch (cst false) (foo x);
> test_bar x::bar = x;
> test_baz x::baz = x;
> test_bar ()
<stdin>, line 6: unhandled exception ‘foo’ while evaluating ‘test_bar ()’
```
> test_baz ();
> test_baz()

Exceptions also provide a way to handle asynchronous signals. Pure’s system module provides symbolic constants for common POSIX signals and also defines the operation trap which lets you rebind any signal to a signal exception. For instance, the following lets you handle the SIGQUIT signal:

```purescript
> using system;
> trap SIG_TRAP SIGQUIT;
```

You can also use trap to just ignore a signal or revert to the system’s default handler (which might take different actions depending on the type of signal, see signal(7) for details):

```purescript
> trap SIG_IGN SIGQUIT; // signal is ignored
> trap SIG_DFL SIGQUIT; // reinstalls the default signal handler
```

Note that when the interpreter runs interactively, for convenience most standard termination signals (SIGINT, SIGTERM, etc.) are already set up to produce corresponding Pure exceptions of the form signal SIG where SIG is the signal number. If a script is to be run non-interactively then you’ll have to do this yourself (otherwise most signals will terminate the program).

While exceptions are normally used to report abnormal error conditions, they also provide a way to implement non-local value returns. For instance, here’s a variation of our n queens algorithm (cf. List Comprehensions) which only returns the first solution. Note the use of throw in the recursive search routine to bail out with a solution as soon as we found one. The value thrown there is caught in the main routine. Also note the use of void in the second equation of search. This effectively turns the list comprehension into a simple loop which suppresses the normal list result and just returns () instead. Thus, if no value gets thrown then the function regularly returns with () to indicate that there is no solution.

```purescript
queens n = catch reverse (search n 1 []) with

  search n i p = throw p if i>n;
  = void [search n (i+1) ((i,j):p) | j = 1..n; safe (i,j) p];

  safe (i,j) p = ~any (check (i,j)) p;

  check (i1,j1) (i2,j2)
  = i1==i2 || j1==j2 || i1+j1==i2+j2 || i1-j1==i2-j2;

end;
```

E.g., let’s compute a solution for a standard 8x8 board:

```purescript
> queens 8;
[(1,1),(2,5),(3,8),(4,6),(5,3),(6,7),(7,2),(8,4)]
```

### 1.9 Standard Library

Pure comes with a collection of Pure library modules, which includes the standard prelude (loaded automatically at startup time) and some other modules which can be loaded explicitly with a using clause. The prelude offers the necessary functions to work with the built-in
types (including arithmetic and logical operations) and to do most kind of list processing you can find in ML- and Haskell-like languages. It also provides a collection of basic string and matrix operations. Please refer to the Pure Library Manual for details on the provided operations. Here is a very brief summary of some of the prelude operations which, besides the usual arithmetic and logical operators, are probably used most frequently:

\[ x + y \]

The arithmetic + operation is also used to denote list and string concatenation in Pure.

\[ x : y \]

This is the list-consing operation. \( x \) becomes the head of the list, \( y \) its tail. As ‘:’ is a constructor symbol, you can use it in patterns on the left hand side of rewriting rules.

\[ x .. y \]

Constructs arithmetic sequences. \( x : y .. z \) can be used to denote sequences with arbitrary stepsize \( y \cdot x \). Infinite sequences can be constructed using an infinite bound (i.e., \( \text{inf} \) or \( -\text{inf} \)). E.g., \( 1:3 .. \text{inf} \) denotes the stream of all odd integers starting at 1.

\[ x, y \]

This is the pair constructor, used to create tuples of arbitrary sizes. Tuples provide an alternative way to represent aggregate values in Pure. In contrast to lists, tuples are always “flat”, so that \( (x, y) \), \( z \) and \( x, (y, z) \) denote the same triple \( x, y, z \). (This is explained in more detail in the Primary Expressions section.)

\[ \#x \]

The size (number of elements) of the list, tuple, matrix or string \( x \). In addition, \( \text{dim } x \) yields the dimensions (number of rows and columns) of a matrix.

\[ x!y \]

This is Pure’s indexing operation, which applies to lists, tuples, matrices and strings. Note that all indices in Pure are zero-based, thus \( x!0 \) and \( x!(\#x-1) \) are the first and last element of \( x \). In the case of matrices, the subscript may also be a pair of row and column indices, such as \( x!(1,2) \).

\[ x!!ys \]

This is the “slicing” operation, which returns the list, tuple, matrix or string of all \( x!y \) while \( y \) runs through the elements of the list or matrix \( ys \). Thus, e.g., \( x!!(i..j) \) returns all the elements between \( i \) and \( j \) (inclusive). Indices which fall outside the valid index range are quietly discarded. The index range \( ys \) may contain any number of indices (also duplicates), in any order. Thus \( x!![0|1=1..n] \) returns the first element of \( x \) \( n \) times, and, if \( ys \) is a permutation of the range \( 0 .. \#x-1 \), then \( x!!ys \) yields the corresponding permutation of the elements of \( x \). In the case of matrices the index range may also contain two-dimensional subscripts, or the index range itself may be specified as a pair of row/column index lists such as \( x!!(i..j,k..l) \).

The prelude also offers support operations for the implementation of list and matrix comprehensions, as well as the customary list operations like \text{head}, \text{tail}, \text{drop}, \text{take}, \text{filter}, \text{map}, \text{foldl}, \text{foldr}, \text{scanl}, \text{scanr}, \text{zip}, \text{unzip}, \text{etc.}, which make list programming so much fun in modern FPLs. In Pure, these also work on strings as well as matrices, although, for reasons of efficiency, these data structures are internally represented as arrays.
Besides the prelude, Pure’s standard library also comprises a growing number of additional library modules which we can only mention in passing here. In particular, the math module provides additional mathematical functions as well as Pure’s complex and rational number data types. Common container data structures like sets and dictionaries are implemented in the set and dict modules, among others. Moreover, the system interface can be found in the system module. In particular, this module also provides operations to do basic C-style I/O, including printf and scanf.

1.10 C Interface

Pure makes it very easy to call C functions (as well as functions in a number of other languages supported by the GNU compiler collection). To call an existing C function, you just need an extern declaration of the function, as described below. By these means, all functions in the standard C library and the Pure runtime are readily available to Pure scripts. Functions can also be loaded from dynamic libraries and LLVM bitcode files at runtime. In the latter case, you don’t even need to write any extern declarations, the interpreter will do that for you. As of Pure 0.45, you can also add inline C/C++ and Fortran code to your Pure scripts and have the Pure interpreter compile them on the fly, provided that you have the corresponding compilers from the LLVM project installed.

In some cases you will still have to rely on big and complicated third-party and system libraries which aren’t readily available in bitcode form. It goes without saying that writing all the extern declarations for such libraries can be a daunting task. Fortunately, there is a utility to help with this, by extracting the extern declarations automatically from C headers. Please see External C Functions in the Caveats and Notes section for details.

1.10.1 Extern Declarations

To access an existing C function in Pure, you need an extern declaration of the function, which is a simplified kind of C prototype. The syntax of these declarations is described by the following grammar rules:

```plaintext
extern_decl ::= [scope] "extern" prototype ("," prototype)* ";"
prototype ::= c_type identifier "(" [parameters | "..."] ")" ["=" identifier]
parameters ::= parameter ("," parameter)* ['"" "..."]
parameter ::= c_type [identifier]
c_type ::= identifier "*"*
```

Extern functions can be called in Pure just like any other. For instance, the following commands, entered interactively in the interpreter, let you use the sin function from the C library (of course you could just as well put the extern declaration into a script):

```plaintext
> extern double sin(double);
> sin 0.3;
0.29552020666134
```

An extern declaration can also be prefixed with a public/private scope specifier:
private extern double sin(double);

Multiple prototypes can be given in one extern declaration, separating them with commas:

extern double sin(double), double cos(double), double tan(double);

For clarity, the parameter types can also be annotated with parameter names (these only serve informational purposes and are for the human reader; they are effectively treated as comments by the compiler):

extern double sin(double x);

Pointer types are indicated by following the name of the element type with one or more asterisks, as in C. For instance:

> extern char* strchr(char *s, int c);
> strchr "foo bar" (ord "b");
> "bar"

As you can see in the previous example, some pointer types get special treatment, allowing you to pass certain kinds of Pure data (such as Pure strings as char* in this example). This is discussed in more detail in C Types below.

The interpreter makes sure that the parameters in a call match; if not, then by default the call is treated as a normal form expression:

> extern double sin(double);
> sin 0.3;
0.29552020666134
> sin 0;
sin 0

This gives you the opportunity to augment the external function with your own Pure equations. To make this work, you have to make sure that the extern declaration of the function comes first. For instance, we might want to extend the sin function with a rule to handle integers:

> sin x::int = sin (double x);
> sin 0;
0.0

Sometimes it is preferable to replace a C function with a wrapper function written in Pure. In such a case you can specify an alias under which the original C function is known to the Pure program, so that you can still call the C function from the wrapper. An alias is introduced by terminating the extern declaration with a clause of the form = alias. For instance:

> extern double sin(double) = c_sin;
> sin x::double = c_sin x;
> sin x::int = c_sin (double x);
> sin 0.3; sin 0;
0.29552020666134
0.0
Aliases are just one way to declare a synonym of an external function. As an alternative, you can also declare the C function in a special namespace (cf. Namespaces in the Declarations section):

```c
> namespace c;
> extern double sin(double);
> c::sin 0.3;
0.29552020666134
```

Note that the namespace qualification only affects the Pure side; the underlying C function is still called under the unqualified name as usual. The way in which such qualified externs are accessed is the same as for ordinary qualified symbols. In particular, the using namespace declaration applies as usual, and you can declare such symbols as private if needed. It is also possible to combine a namespace qualifier with an alias:

```c
> namespace c;
> extern double sin(double) = mysin;
> c::mysin 0.3;
0.29552020666134
```

In either case, different synonyms of the same external function can be declared in slightly different ways, which makes it possible to adjust the interpretation of pointer values on the Pure side. This is particularly useful for string arguments which, as described below, may be passed both as char* (which implies copying and conversion to or from the system encoding) and as void* (which simply passes through the character pointers). For instance:

```c
> extern char *strchr(char *s, int c) = foo;
> extern void *strchr(void *s, int c) = bar;
> foo "foo bar" 98; bar "foo bar" 98;
"bar"
#<pointer 0x12c2f24>
```

Also note that, as far as Pure is concerned, different synonyms of an external function are really different functions. In particular, they can each have their own set of augmenting Pure equations. For instance:

```c
> extern double sin(double);
> extern double sin(double) = mysin;
> sin === sin;
1
> sin === mysin;
0
> sin 1.0; mysin 1.0;
0.841470984807897
0.841470984807897
> sin x::int = sin (double x);
> sin 1; mysin 1;
0.841470984807897
mysin 1
```
1.10.2 Variadic C Functions

Variadic C functions are declared as usual by terminating the parameter list with an ellipsis (...):

```c
> extern int printf(char*, ...);
> printf "Hello, world\n";
Hello, world
13
```

Note that the variadic prototype is mandatory here, since the compiler needs to know about the optional arguments so that it can generate the proper code to call the function. However, in Pure a function always has a fixed arity, so, as far as Pure is concerned, the function is still treated as if it had no extra arguments. Thus the above declaration only allows you to call `printf` with a single argument.

To make it possible to pass optional arguments to a variadic function, you must explicitly give the (non-variadic) prototypes with which the function is to be called. To these ends, the additional prototypes are declared as synonyms of the original variadic function. This works because the compiler only checks the non-variadic parameters for conformance. For instance:

```c
> extern int printf(char*, char*) = printf_s;
> printf_s "Hello, %s\n" "world";
Hello, world
13
> extern int printf(char*, int) = printf_d;
> printf_d "Hello, %d\n" 99;
Hello, 99
10
```

1.10.3 C Types

As indicated in the previous section, the data types in `extern` declarations are either C type names or pointer types derived from these. The special `expr*` pointer type is simply passed through; this provides a means to deal with Pure data in C functions in a direct fashion. For all other C types, Pure values are “marshalled” (converted) from Pure to C when passed as arguments to C functions, and the result returned by the C function is then converted back from C to Pure. All of this is handled by the runtime system in a transparent way, of course.

Note that, to keep things simple, Pure does not provide any notations for C structs or function types, although it is possible to represent pointers to such objects using `void*` or some other appropriate pointer types. In practice, this simplified system should cover most kinds of calls that need to be done when interfacing to C libraries, but there are ways to work around these limitations if you need to access C structs or call back from C to Pure, see External C Functions in the Caveats and Notes section for details.

Basic C Types

Pure supports the usual range of basic C types: `void`, `bool`, `char`, `short`, `int`, `long`, `float`, `double`, and converts between these and the corresponding Pure data types (machine ints,
bigints and double values) in a straightforward way.

The void type is only allowed in function results. It is converted to the empty tuple ()

Both float and double are supported as floating point types. Single precision float arguments and return values are converted from/to Pure’s double precision floating point numbers.

A variety of C integer types (bool, char, short, int, long) are provided which are converted from/to the available Pure integer types in a straightforward way. In addition, the synonyms int8, int16 and int32 are provided for char, short and int, respectively, and int64 denotes 64 bit integers (a.k.a. ISO C99 long long). Note that long is equivalent to int32 on 32 bit systems, whereas it is the same as int64 on most 64 bit systems. To make it easier to interface to various system routines, there’s also a special sizeof integer type which usually is 4 bytes on 32 bit and 8 bytes on 64 bit systems.

All integer parameters take both Pure ints and bigints as actual arguments; truncation or sign extension is performed as needed, so that the C interface behaves as if the argument was “cast” to the C target type. Returned integers use the smallest Pure type capable of holding the result, i.e., int for the C char, short and int types, bigint for int64.

Pure considers all integers as signed quantities, but it is possible to pass unsigned integers as well (if necessary, you can use a bigint to pass positive values which are too big to fit into a machine int). Also note that when an unsigned integer is returned by a C routine, which is too big to fit into the corresponding signed integer type, it will “wrap around” and become negative. In this case, depending on the target type, you can use the ubyte, ushort, uint, ulong and uint64 functions provided by the prelude to convert the result back to an unsigned quantity.

**Pointer Types**

The use of pointer types is also fairly straightforward, but Pure has some special rules for the conversion of certain pointer types which make it easy to pass aggregate Pure data to and from C routines, while also following the most common idioms for pointer usage in C. The following types of pointers are recognized both as arguments and return values of C functions.

Bidirectional pointer conversions:

- char* is used for string arguments and return values which are converted from Pure’s internal utf-8 based string representation to the system encoding and vice versa. (Thus a C routine can never modify the raw Pure string data in-place; if this is required then you’ll have to pass the string argument as a void*, see below.)

- void* is for any generic pointer value, which is simply passed through unchanged. When used as an argument, you can also pass Pure strings, matrices and bigints. In this case the raw underlying data pointer (char* in the case of strings, int*, double* or expr* in the case of numeric and symbolic matrices, and the GMP type mpz_t in the case of bigints) is passed, which allows the data to be modified in place (with care). In particular, passing bigints as void* makes it possible to call most GMP integer routines directly from Pure.
• `dmatrix*`, `cmatrix*` and `imatrix*` allow you to pass numeric Pure matrices of the appropriate types (double, complex, int). Here a pointer to the underlying GSL matrix structure is passed (not just the data itself). This makes it possible to transfer GSL matrices between Pure and GSL routines in a direct fashion without any overhead. (For convenience, there are also some other pointer conversions for marshalling matrix arguments to numeric C vectors, which are described in Pointers and Matrices below.)

• `expr*` is for any kind of Pure value. A pointer to the expression node is passed to or from the C function. This type is to be used for C routines which are prepared to deal with pristine Pure data, using the corresponding functions provided by the runtime. You can find many examples of this in the standard library.

All other pointer types are simply taken at face value, allowing you to pass Pure pointer values as is, without any conversions. This also includes pointers to arbitrary named types which don’t have a predefined meaning in Pure, such as `FILE*`. As of Pure 0.45, the interpreter keeps track of the actual names of all pointer types and checks (at runtime) that the types match in an external call, so that you can’t accidentally get a core dump by passing, say, a `FILE*` for a `char*`. (The call will then simply fail and yield a normal form, which gives you the opportunity to hook into the function with your own Pure definitions which may supply any desired data conversions.) Typing information about pointer values is also available to Pure scripts by means of corresponding library functions, please see the Tagged Pointers section in the Pure Library Manual for details.

Pointers and Matrices

The following additional pointer conversions are provided to deal with Pure matrix values in arguments of C functions, i.e., on the input side. These enable you to pass Pure matrices for certain kinds of C vectors. Note that in any case, you can also simply pass a suitable plain pointer value instead. Also, these types aren’t special in return values, where they will simply yield a pointer value (with the exception of `char*` which gets special treatment as explained in the previous subsection). Thus you will have to decode such results manually if needed. The standard library provides various routines to do this, please see the String Functions and Matrix Functions sections in the Pure Library Manual for details.

Numeric pointer conversions (input only):

• `char*`, `short*`, `int*`, `int64*`, `float*`, `double*` can be used to pass numeric matrices as C vectors. This kind of conversion passes just the matrix data (not the GSL matrix structure, as the `dmatrix*` et al conversions do) and does conversions between integer or floating point data of different sizes on the fly. You can either pass an int matrix as a `char*`, `short*` `int*` or `int64*` argument, or a double or complex matrix as a `float*` or `double*` argument (complex values are then represented as two separate double numbers, first the real, then the imaginary part, for each matrix element).

• `char**`, `short**`, `int**`, `int64**`, `float**`, `double**` provide yet another way to pass numeric matrix arguments. This works analogously to the numeric vector conversions above, but here a temporary C vector of pointers is passed to the C function, whose elements point to the rows of the matrix.

Argv-style conversions (input only):
char** and void** can be used to pass argv-style vectors as arguments to C functions. In this case, the Pure argument must be a symbolic vector of strings or generic pointer values. char** converts the string elements to the system encoding, whereas void** passes through character string data and other pointers unchanged (and allows in-place modification of the data). A temporary C vector of these elements is passed to the C function, which is always NULL-terminated and can thus be used for almost any purpose which requires such argv-style vectors.

Note that in the numeric pointer conversions, the matrix data is passed “per reference” to C routines, i.e., the C function may modify the data “in place”. This is true even for target data types such as short* or float** which involve automatic conversions and hence need temporary storage. In this case the data from the temporary storage is written back to the original matrix when the function returns, to maintain the illusion of in-place modification. Temporary storage is also needed when the GSL matrix has the data in non-contiguous storage. You may want to avoid this if performance is critical, by always using “packed” matrices (see pack in Matrix Functions) of the appropriate types.

**Pointer Examples**

Let’s finally have a look at some instructive examples to explain some of the trickier pointer types.

First, the matrix pointer types dmatrix*, cmatrix* and imatrix* can be used to pass double, complex double and int matrices to GSL functions taking pointers to the corresponding GSL types (gsl_matrix, gsl_matrix_complex and gsl_matrix_int) as arguments or returning them as results. (Note that there is no special marshalling of Pure’s symbolic matrix type, as these aren’t supported by GSL anyway.) Also note that matrices are always passed by reference. Thus, if you need to pass a matrix as an output parameter of a GSL matrix routine, you should either create a zero matrix or a copy of an existing matrix to hold the result. The prelude provides various operations for that purpose (in particular, see the dmatrix, cmatrix, imatrix and pack functions in matrices.pure). For instance, here is how you can quickly wrap up GSL’s double matrix addition function in a way that preserves value semantics:

```pure
> using "lib:gsl";
> extern int gsl_matrix_add(dmatrix*, dmatrix*);
> x::matrix + y::matrix = gsl_matrix_add x y $$ x = pack x end;
> let x = dmatrix {1,2,3}; let y = dmatrix {2,3,2}; x; y; x+y;
{1.0,2.0,3.0}
{2.0,3.0,2.0}
{3.0,5.0,5.0}
```

Most GSL matrix routines can be wrapped in this fashion quite easily. A ready-made GSL interface providing access to all of GSL’s numeric functions is in the works; please check the Pure website for details.

For convenience, it is also possible to pass any kind of numeric matrix for a char*, short*, int*, int64*, float* or double* parameter. This requires that the pointer and the matrix type match up; conversions between char, short, int64 and int data and, likewise, between float and double are handled automatically, however. For instance, here is how you can call
the `puts` routine from the C library with an int matrix encoding the string "Hello, world!" as byte values (ASCII codes):

```plaintext
> extern int puts(char*);
Hello, world!
```

Pure 0.45 and later also support `char**`, `short**`, `int**, `int64**`, `float**` and `double**` parameters which encode a matrix as a vector of row pointers instead. This kind of matrix representation is often found in audio and video processing software (where the rows of the matrix might denote different audio channels, display lines or video frames), but it’s also fairly convenient to do any kind of matrix processing in C. For instance, here’s how to do matrix multiplication (the naive algorithm):

```c
void matmult(int n, int l, int m, double **x, double **y, double **z)
{
    int i, j, k;
    for (i = 0; i < n; i++)
        for (j = 0; j < m; j++) {
            z[i][j] = 0.0;
            for (k = 0; k < l; k++)
                z[i][j] += x[i][k]*y[k][j];
        }
}
```

As you can see, this multiplies a \( n \times l \) matrix \( x \) with a \( l \times m \) matrix \( y \) and puts the result into the \( n \times m \) matrix \( z \):

```plaintext
> extern void matmult(int, int, int, double **, double **, double **);
> let x = {0.11,0.12,0.13;0.21,0.22,0.23};
> let y = {1011.0,1012.0;1021.0,1022.0;1031.0,1032.0};
> let z = dmatrix (2,2);
> matmult 2 3 2 x y z $$ z;
{367.76,368.12;674.06,674.72}
```

Also new in Pure 0.45 is the support for passing `argv`-style vectors as arguments. For instance, here is how you can use `fork` and `execvp` to implement a poor man’s version of the C `system` function. (This is Unix-specific and doesn’t do much error-checking, but you get the idea.)

```c
extern int fork();
extern int execvp(char *path, char **argv);
extern int waitpid(int pid, int *status, int options);

system cmd::string = case fork of
    // child: execute the program, bail out if error
    0 = execvp "'/bin/sh" {"'/bin/sh","-c",cmd} $$ exit 1;
    // parent: wait for the child and return its exit code
    pid = waitpid pid status 0 $$ status!0 >> 8
    when status = {0} end if pid>=0;
end;
```
system "echo Hello, world!";
system "ls -l *.pure";
system "exit 1";

1.10.4 Importing Dynamic Libraries

By default, external C functions are resolved by the LLVM runtime, which first looks for
the symbol in the C library and Pure’s runtime library (or the interpreter executable, if the
interpreter was linked statically). Thus all C library and Pure runtime functions are readily
available in Pure programs. Other functions can be provided by adding them to the runtime,
or by linking them into the runtime or the interpreter executable. Better yet, you can just
“dlopen” shared libraries at runtime with a special form of the using clause:

using "lib:libname[.ext]";

For instance, if you want to call the functions from library libxyz directly from Pure:

using "lib:libxyz";

After this declaration the functions from the given library will be ready to be imported into
your Pure program by means of corresponding extern declarations.

Shared libraries opened with using clauses are searched for in the same way as source scripts
(see section Modules and Imports above), using the -L option and the PURE_LIBRARY envi-
ronment variable in place of -I and PURE_INCLUDE. If the library isn’t found by these means,
the interpreter will also consider other platform-specific locations searched by the dynamic
linker, such as the system library directories and LD_LIBRARY_PATH on Linux. The necessary
filename suffix (e.g., .so on Linux or .dll on Windows) will be supplied automatically when
needed. Of course you can also specify a full pathname for the library if you prefer that. If
a library file cannot be found, or if an extern declaration names a function symbol which
cannot be resolved, an appropriate error message is printed.

1.10.5 Importing LLVM Bitcode

As of Pure 0.44, the interpreter also provides a direct way to import LLVM bitcode modules
in Pure scripts. The main advantage of this method over the “plain” C interface explained
above is that the bytecode loader knows all the call interfaces and generates the necessary
extern declarations automatically. This is more than just a convenience, as it also eliminates
at least some of the mistakes in extern declarations that may arise when importing functions
manually from dynamic libraries.

Note: The facilities described below require that you have an LLVM-capable C/C++ com-
piler installed. The available options right now are clang, llvm-gcc and dragonegg. Please
check the Pure installation instructions on how to get one of these (or all of them) up and run-
ning. Note that clang and llvm-gcc are standalone compilers, while dragonegg is supplied
as a gcc plugin which hooks into your existing system compiler (gcc 4.5 or later is required
for that). Any of these enable you to compile C/C++ source to LLVM assembler or bitcode.
The clang compiler is recommended for C/C++ development, as it offers faster compilation
times and has much better diagnostics than gcc. On the other hand, llvm-gcc and dragonegg have the advantage that they also support alternative frontends so that you can compile Fortran and Ada code as well. (But note that, as of LLVM 3.x, llvm-gcc is not supported any more.)

LLVM bitcode is loaded in a Pure script using the following special format of the using clause:

```plaintext
using "bc:modname[.bc]";
```

(Here the bc tag indicates a bitcode file, and the default .bc bitcode filename extension is supplied automatically. Also, the bitcode file is searched for on the usual library search path.)

That’s it, no explicit extern declarations are required on the Pure side. The Pure interpreter automatically creates extern declarations (in the current namespace) for all the external functions defined in the LLVM bitcode module, and generates the corresponding wrappers to make the functions callable from Pure. (This also works when batch-compiling a Pure script. In this case, the bitcode file actually gets linked into the output code, so the loaded bitcode module only needs to be present at compile time.)

By default the imported symbols will be public. You can also specify the desired scope of the symbols explicitly, by placing the public or private keyword before the module name. For instance:

```plaintext
using private "bc:modname";
```

You can also import the same bitcode module several times, possibly in different namespaces. This will not actually reload the module, but it will create synonyms for the external functions in different namespaces:

```plaintext
namespace foo;
using "bc:modname";
namespace bar;
using private "bc:modname";
```

You can load any number of bitcode modules along with shared libraries in a Pure script, in any order. The JIT will try to satisfy external references in modules and libraries from other loaded libraries and bitcode modules. This is deferred until the code is actually JIT-compiled, so that you can make sure beforehand that all required libraries and bitcode modules have been loaded. If the JIT fails to resolve a function, the interpreter will print its name and also raise an exception at runtime when the function is being called from other C code. (You can then run your script in the debugger to locate the external visible in Pure from which the unresolved function is called.)

Let’s take a look at a concrete example to see how this actually works. Consider the following C code which defines a little function to compute the greatest common divisor of two (machine) integers:
int mygcd(int x, int y)
{
    if (y == 0)
        return x;
    else
        return mygcd(y, x % y);
}

Let's say that this code is in the file mygcd.c, then you'd compile it to a bitcode module using clang as follows:

clang -emit-llvm -c mygcd.c -o mygcd.bc

Note that the -emit-llvm -c options instruct clang to build an LLVM bitcode module. Of course, you can also add optimizations and other options to the compile command as desired.

Using dragonegg is somewhat more involved, as it doesn’t provide a direct way to produce a bitcode file yet. However, you can create an LLVM assembler file which can then be translated to bitcode using the llvma-s program as follows:

gcc -fplugin=dragonegg -flto -S mygcd.c -o mygcd.ll
llvm-as mygcd.ll -o mygcd.bc

(Note that the -fplugin option instructs gcc to use the dragonegg plugin, which in conjunction with the -flto flag switches it to LLVM output. Please check the dragonegg website for details.)

In either case, you can now load the resulting bitcode module and run the mygcd function in the Pure interpreter simply as follows:

> using "bc:mygcd";
> mygcd 75 105;
15

To actually see the generated extern declaration of the imported function, you can use the interactive show command:

> show mygcd
extern int mygcd(int, int);

Some more examples showing how to use the bitcode interface can be found in the Pure sources. In particular, the interface also works with Fortran (using llvm-gfortran or gfortran with dragonegg), and there is special support for interfacing to Grame’s functional DSP programming language Faust (the latter uses a special variant of the bitcode loader, which is selected with the dsp tag in the using clause). Further details about these can be found below.

Please note that at this time the LLVM bitcode interface is still somewhat experimental, and there are some known limitations:

- LLVM doesn’t distinguish between char* and void* in bitcode, so all void* parameters
and return values in C code will be promoted to char* on the Pure side. Also, pointers to types which neither have a predefined meaning in Pure nor a proper type name in the bitcode file, will become a generic pointer type (void*, void**, etc.) in Pure. If this is a problem then you can just redeclare the corresponding functions under a synonym after loading the bitcode module, giving the proper argument and result types (see Extern Declarations above). For instance:

```plaintext
> using "bc:foo";
> show foo
extern char* foo(char*);
> extern void* foo(void*) = myfoo;
> show myfoo
extern void* foo(void*) = myfoo;
```

• The bitcode interface is limited to the same range of C types as Pure’s plain C interface. In practice, this should cover most C code, but it’s certainly possible that you run into unsupported types for arguments and return values. The compiler will then print a warning; the affected functions will still be linked in, but they will not be callable from Pure. Also note that calling conventions for passing C structs by value depend on the host ABI, so you should have a look at the resulting extern declaration (using show) to determine how the function is actually to be called from Pure.

### 1.10.6 Inline Code

Instead of manually compiling source files to bitcode modules, you can also just place the source code into a Pure script, enclosing it in %< ... %>. (Optionally, the opening brace may also be preceded with a public or private scope specifier, which is used in the same way as the scope specifier following the using keyword when importing bitcode files.)

For instance, here is a little script showing inline code for the mygcd function from the previous subsection:

```plaintext
%<
int mygcd(int x, int y)
{
    if (y == 0)
        return x;
    else
        return mygcd(y, x%y);
}
%>

mygcd 75 105;
```

The interpreter automatically compiles the inlined code to LLVM bitcode which is then loaded as usual. (Of course, this will only work if you have the corresponding LLVM compilers installed.) This method has the advantage that you don’t have to write a Makefile and you can create self-contained Pure scripts which include all required external functions. The downside is that the inline code sections will have to be recompiled every time you run the script with the interpreter which may considerably increase startup times. If this is a
problem then it’s usually better to import a separate bitcode module instead (see Importing LLVM Bitcode), or batch-compile your script to an executable (see Batch Compilation).

At present, C, C++, Fortran, ATS and Faust are supported as foreign source languages, with clang, clang++, gfortran (with the dragonegg plugin), patscc and faust as the corresponding (default) compilers. C is the default language. The desired source language can be selected by placing an appropriate tag into the inline code section, immediately after the opening brace. (The tag is removed before the code is submitted to compilation.) For instance:

```plaintext
%< -*- Fortran90 -*-
function fact(n) result(p)
  integer n, p
  p = 1
  do i = 1, n
    p = p*i
  end do
end function fact
%>

fact n::int = fact_ {n};
map fact (1..10);
```

As indicated, the language tag takes the form `*- lang -*` where `lang` can currently be any of c, c++, fortran, ats and dsp (the latter indicates the Faust language). Case is insignificant here, so you can also write C, C++, Fortran, ATS, DSP etc. For the fortran tag, you may also have to specify the appropriate language standard, such as fortran90 which is used in the example above. The language tag can also be followed by a module name, using the format `*- lang:name -*`. This is optional for all languages except Faust (where the module name specifies the namespace for the interface routines of the Faust module; see Interfacing to Faust below). So, e.g., a Faust DSP named test would be specified with a dsp: test tag. Case is significant in the module name.

The Pure interpreter has some built-in knowledge on how to invoke the LLVM compilers to produce a working bitcode file ready to be loaded by the interpreter, so the examples above should work out of the box if you have the required compilers installed on your PATH. However, there are also some environment variables you can set for customization purposes. Specifically, PURE_CC is the command to invoke the C compiler. This variable lets you specify the exact name of the executable along with any debugging and optimization options that you may want to add. Likewise, PURE_CXX, PURE_FC, PURE_ATS and PURE_FAUST are used for the C++, Fortran, ATS and Faust compilers, respectively.

For instance, if you prefer to use llvm-gcc as your C compiler, and you’d like to invoke it with the -O3 optimization option, you would set PURE_CC to "llvm-gcc -O3". (To verify the settings you made, you can have the interpreter echo the compilation commands which are actually executed, by running Pure with the -v0100 option, see Verbosity and Debugging Options. Also note that the options necessary to produce LLVM bitcode will be added automatically, so you don’t have to specify these.)

Beginning with Pure 0.48, the dragonegg gcc plugin is also fully supported. To make this work, you need to explicitly specify the name of the plugin in the compilation command, so
that the Pure interpreter can add the proper set of options needed for bitcode compilation. For instance:

```
PURE_CC="gcc -fplugin=dragonegg -O3"
```

Some further details on the bitcode support for specific target languages can be found in the subsections below.

### 1.10.7 Interfacing to C++

Interfacing to C++ code requires additional preparations because of the name mangling performed by C++ compilers. Usually, you won’t be able to call C++ functions and methods directly, so you’ll have to expose the required functionality using functions with C binding (extern "C"). For instance, the following example shows how to work with STL maps from Pure.

```c++
#include <pure/runtime.h>
#include <string>
#include <map>

using namespace std;

typedef map<string,pure_expr*> exprmap;

// An STL map mapping strings to Pure expressions.

// Since we can’t directly deal with C++ classes in Pure, provide some C functions to create, destroy and manipulate these objects.

extern "C" exprmap *map_create()
{
    return new exprmap;
}

extern "C" void map_add(exprmap *m, const char *key, pure_expr *x)
{
    exprmap::iterator it = m->find(string(key));
    if (it != m->end()) pure_free(it->second);
    (*m)[key] = pure_new(x);
}

extern "C" void map_del(exprmap *m, const char *key)
{
    exprmap::iterator it = m->find(key);
    if (it != m->end()) {
        pure_free(it->second);
        m->erase(it);
    }
}

extern "C" pure_expr *map_get(exprmap *m, const char *key)
```
{  
exprmap::iterator it = m->find(key);  
return (it != m->end())?it->second:0;
}

extern "C" pure_expr *map_keys(exprmap *m)  
{  
sizet i = 0, n = m->size();  
pure_expr **xs = new pure_expr*[n];  
for (exprmap::iterator it = m->begin(); it != m->end(); ++it)  
    xs[i++] = pure_string_dup(it->first.c_str());  
pure_expr *x = pure_listv(n, xs);  
delete[] xs;  
return x;
}

extern "C" void map_destroy(exprmap *m)  
{  
for (exprmap::iterator it = m->begin(); it != m->end(); ++it)  
pure_free(it->second);  
delete m;
}

// Create the STL map and add a sentry so that it garbage-collects itself.  
let m = sentry map_destroy map_create;

// Populate the map with some arbitrary Pure data.  
do (
(x=>y) -> map_add m x y) ["foo"=>99, "bar"=>bar 4711L, "baz"=>1..5];

// Query the map.  
map_keys m; // => ["bar","baz","foo"]
map (map_get m) (map_keys m); // => [bar 4711L,[1,2,3,4,5],99]

// Delete an element.  
map_del m "foo";
map_keys m; // => ["bar","baz"]
map (map_get m) (map_keys m); // => [bar 4711L,[1,2,3,4,5]]

1.10.8 Interfacing to ATS

ATS is a statically typed functional programming language somewhat similar to ML, which also offers imperative and concurrent programming features. One of ATS’s most unusual and interesting aspects is its highly expressive Applied Type System, which gives the language its name. ATS has a very elaborate C interface which lets you expose functions written in the language using C linkage. This makes it easy to call ATS functions from Pure via Pure’s C interface.

Here is a simple example which illustrates how to implement the factorial in ATS and call that function from Pure:
%< -*- ATS -*-
#include "share/atspre_staload.hats"

// A recursive definition of the factorial relation.
// FACT (n, r) means 'the factorial of n equals r'.
// MUL (i, j, k) means 'the product of i and j equals k'.
dataprop FACT (int, int) =
  | FACT_base (0, 1)
  | \{n : nat\} \{r1, r : int\} FACT_induction (n, r) of
    (FACT (n-1, r1), MUL (n, r1, r))

// Declare ifact as an ATS function that is referred to in C by the
// name 'ifact_nonneg'. The 'ifact_nonneg' function returns an integer
// equal to r, where r satisfies the relation FACT (n, r).
extern fun ifact :
  \{n : nat\} (int n) -<> \[r : int\] (FACT (n, r) | int r) =
  "ext#ifact_nonneg"

implement ifact (n) =
  let
    fun fact {n : nat}.<n>. (n : int n) -<> \[r : int\] (FACT (n, r) | int r) =
      begin
        if n > 0 then
          let
            val (pf1 | r1) = ifact (n - 1)
            val (pfmul | r) = g1int_mul2 (n, r1)
          in
            (FACT_induction (pf1, pfmul) | r)
          end
        else
          (FACT_base () | 1)
        end
      in
    fact n
  end

ifact n::int = ifact_nonneg n if 0 <= n;

map ifact (0..9);
More information about ATS, as well as sources and binary packages of the ATS compiler can be found on the ATS website.

### 1.10.9 Interfacing to Faust

**Faust** is a functional dsp (digital signal processing) programming language developed at Grame, which is tailored to the task of generating and transforming streams of numeric data at the sample level. It is typically used to program sound synthesis and audio effect units, but can in fact be employed to process any kind of numeric vector and matrix data. The Faust compiler is capable of generating very efficient code for such tasks which is comparable in performance with carefully handcrafted C routines. Pure’s Faust interface lets you use these capabilities in order to process sample data stored in Pure matrices.

Pure’s LLVM bitcode loader has some special knowledge about Faust built into it, which makes interfacing to Faust programs simple and efficient. You’ll need a recent LLVM-capable version of Faust (Faust 2.0 or later, abbreviated “Faust2” in the following) to make this work.

| Note: | There’s also an alternative interface to Faust which is available as a separate package, please check the [pure-faust](https://example.com) package for details. This package also provides the [faust2](https://example.com) compatibility module which implements the pure-faust API on top of Pure’s built-in Faust interface, so that you can also use the operations of this module instead. (The pure-faust API can in fact be more convenient to use in some cases, especially if you want to load a lot of different Faust modules dynamically at runtime.) |

The -lang llvm option instructs the Faust compiler to output LLVM bitcode. Also, you want to add the -double option to make the compiled Faust module use double precision floating point values for samples and control values. So you’d compile an existing Faust module in the source file example.dsp as follows:

```
faust -double -lang llvm example.dsp -o example.bc
```

The -double option isn’t strictly necessary, but it makes interfacing between Pure and Faust easier and more efficient, since Pure uses double as its native floating point format.

Alternatively, you can also use the Faust pure.c architecture (included in recent Faust2 revisions and also in the [pure-faust](https://example.com) package) to compile a Faust program to corresponding C source which can then be fed into an LLVM-capable C compiler to produce bitcode which is compatible with Pure’s Faust bitcode loader. This is useful, in particular, if you want to make use of special optimization options provided by the C compiler, or if the Faust module needs to be linked against additional C/C++ code. For instance:

```
faust -double -a pure.c -lang c example.dsp -o example.c
clang -emit-llvm -O3 -c example.c -o example.bc
```

The [pure-faust](https://example.com) package contains a little helper script `faust2pure` (also available in recent Faust revisions) which makes this a lot easier, so that you can simply write:

```
faust2pure -double -bitcode example.dsp
```
A third possibility is to just inline Faust code in a Pure script, as described in the Inline Code section. The compilation step is then handled by the Pure compiler and the -double option is added automatically. The PURE_FAUST environment variable can be used to specify a custom Faust command to be invoked by the Pure interpreter. This is useful if you’d like to invoke the Faust compiler with some special options, e.g.:

```bash
PURE_FAUST="faust -single -vec"
```

(Note that you do not have to include the -lang llvm option; the inline compiler will supply it automatically.)

Moreover, you can also set the FAUST_OPT environment variable to specify any needed post-processing of the output of the Faust compiler; this is typically used to invoke the LLVM opt utility in a pipeline, in order to have some additional optimizations performed on the Faust-generated code:

```bash
FAUST_OPT="| opt -O3"
```

After loading or inlining the Faust module, the Pure compiler makes the interface routines of the Faust module available in its own namespace. Thus, e.g., the interface routines for the example.dsp module will end up in the example namespace.

Pure’s Faust interface offers another useful feature not provided by the general bitcode interface, namely the ability to reload Faust modules on the fly. If you repeat the import clause for a Faust module, the compiler checks whether the module was modified and, if so, replaces the old module with the new one. Retyping an inline Faust code section has the same effect. This is mainly intended as a convenience for interactive usage, so that you can test different versions of a Faust module without having to restart the Pure interpreter. But it is also put to good use in addon packages like pd-faust which allows Faust dsps to be reloaded at runtime.

For instance, consider the following little Faust program, which takes a stereo audio signal as input, mixes the two channels and multiplies the resulting mono signal with a gain value given by a corresponding Faust control variable:

```faust
gain = nentry("gain", 0.3, 0, 10, 0.01);
process = + : *(gain);
```

The interface routines of this Faust module look as follows on the Pure side:

```c
> show -g example::*
extern void buildUserInterface(struct_dsp_example*, struct_UIGlue*) = example::buildUserInterface;
extern void classInit(int) = example::classInit;
extern void compute(struct_dsp_example*, int, double**, double**) = example::compute;
extern void delete(struct_dsp_example*) = example::delete;
extern void destroy(struct_dsp_example*) = example::destroy;
extern int getNumInputs(struct_dsp_example*) = example::getNumInputs;
extern int getNumOutputs(struct_dsp_example*) = example::getNumOutputs;
extern int getSampleRate(struct_dsp_example*) = example::getSampleRate;
extern expr* info(struct_dsp_example*) = example::info;
extern void init(struct_dsp_example*, int) = example::init;
extern void instanceInit(struct_dsp_example*, int) = example::instanceInit;
```
The most important interface routines are `new`, `newinit` and `delete` (used to create, initialize and destroy an instance of the dsp) and `compute` (used to apply the dsp to a given block of samples). Some useful convenience functions are added by the Pure compiler:

- `newinit` combines `new` and `init`;
- `info` yields pertinent information about the dsp as a Pure tuple containing the number of input and output channels and the Faust control descriptions;
- `meta` yields metadata about the dsp, as declared in the Faust source.

The latter two are provided in a symbolic format ready to be used in Pure; more about that below.

Note that there’s usually no need to explicitly invoke the `delete` routine in Pure programs; the Pure compiler makes sure that this routine is added automatically as a finalizer (see `sentry`) to all dsp pointers created through the `new` and `newinit` routines so that dsp instances are destroyed automatically when the corresponding Pure objects are garbage-collected. (If you prefer to do the finalization manually then you must also remove the `sentry` from the dsp object, so that it doesn’t get deleted twice.)

Another point worth mentioning here is that the Pure compiler always generates code that ensures that the Faust dsp instances (the `struct dsp` pointers) are fully typechecked at runtime. Thus it is only possible to pass a dsp struct pointer to the interface routines of the Faust module it was created with.

Let’s have a brief look at how we can actually run a Faust module in Pure to process some audio samples.

**Step 1: Load the Faust dsp.** This assumes that the Faust source has already been compiled to a bitcode file, as shown above. You can then load the module in Pure as follows:

```pure
> using "dsp:example";
```

Note that the `.bc` bitcode extension is supplied automatically. Also note the special `dsp` tag; this tells the compiler that this is a Faust-generated module, so that it does some Faust-specific processing while linking the module.

Alternatively, you can also just inline the code of the Faust module. For the example above, the inline code section looks as follows:

```pure
%< -*- dsp:example -*-.
gain = nentry("gain", 0.3, 0, 10, 0.01);
process = + : *(gain);
%>
```

You can either add this code to a Pure script, or just type it directly in the Pure interpreter.

---

**1.10.9 Interfacing to Faust**
Finally, you may want to verify that the module has been properly loaded by typing `show -g example::*`. The output should look like the listing above.

**Step 2: Create and initialize a dsp instance.** After importing the Faust module you can now create an instance of the Faust signal processor using the `newinit` routine, and assign it to a Pure variable as follows:

```pure
> let dsp = example::newinit 44100;
```

Note that the constant 44100 denotes the desired sample rate in Hz. This can be an arbitrary integer value, which is available in the Faust program by means of the `SR` variable. It’s completely up to the dsp whether it actually uses this value in some way (our example doesn’t, but we need to specify a value anyway).

The dsp is now fully initialized and we can use it to compute some samples. But before we can do this, we’ll need to know how many channels of audio data the dsp consumes and produces, and which control variables it provides. This information can be extracted with the `info` function, and be assigned to some Pure variables as follows:

```pure
> let k, l, ui = example::info dsp;
```

(We’ll have a closer look at the contents of the `ui` variable below.)

In a similar fashion, the `meta` function provides some “metadata” about the Faust dsp, as a list of key=>val string pairs. This is static data which doesn’t belong to any particular dsp instance, so it can be extracted without actually creating an instance. In our case the metadata will be empty, since we didn’t supply any in the Faust program. If needed, we can add some metadata as follows:

```pure
declare descr "Faust Hello World";
declare author "Faust Guru";
declare version "1.0";
gain = nentry("gain", 0.3, 0, 10, 0.01);
process = + : *(gain);
```

If we now reload the Faust dsp, we’ll get:

```pure
> test::meta;
["descr"="Faust Hello World","author"="Faust Guru","version"="1.0"]
```

**Step 3: Prepare input and output buffers.** Pure’s Faust interface allows you to pass Pure double matrices as sample buffers, which makes this step quite convenient. For given numbers \( k \) and \( l \) of input and output channels, respectively, we’ll need a \( k \times n \) matrix for the input and a \( l \times n \) matrix for the output, where \( n \) is the desired block size (the number of samples to be processed per channel in one go). Note that the matrices have one row per input or output channel. Here’s how we can create some suitable input and output matrices using a Pure matrix comprehension and the `dmatrix` function available in the standard library:

```pure
> let n = 10; // the block size
> let in = \{i*10.0+j | i = 1..k; j = 1..n\};
> let out = dmatrix (l,n);
```
In our example, k=2 and l=1, thus we obtain the following matrices:

\[
\text{in};
\begin{bmatrix}
11.0,12.0,13.0,14.0,15.0,16.0,17.0,18.0,19.0,20.0; \\
21.0,22.0,23.0,24.0,25.0,26.0,27.0,28.0,29.0,30.0
\end{bmatrix}
\]

\[
\text{out};
\begin{bmatrix}
0.0,0.0,0.0,0.0,0.0,0.0,0.0,0.0,0.0,0.0
\end{bmatrix}
\]

**Step 4: Apply the dsp to compute some samples.** With the in and out matrices as given above, we can now apply the dsp by invoking its compute routine:

\[
> \text{example::compute dsp n in out;}
\]

This takes the input samples specified in the in matrix and stores the resulting output in the out matrix. The output matrix now looks as follows:

\[
> \text{out;}
\begin{bmatrix}
9.6,10.2,10.8,11.4,12.0,12.6,13.2,13.8,14.4,15.0
\end{bmatrix}
\]

Note that the compute routine also modifies the internal state of the dsp instance so that a subsequent call will continue with the output stream where the previous call left off. (This isn’t relevant in this specific example, but in general a Faust dsp may contain delays and similar constructions which need a memory of past samples to be maintained between different invocations of compute.) Thus we can now just keep on calling compute (possibly with different in buffers) to compute as much of the output signal as we need.

**Step 5: Inspecting and modifying control variables.** Recall that our sample dsp also has a Faust control variable gain which lets us change the amplification of the output signal. We’ve already assigned the corresponding information to the ui variable, let’s have a look at it now:

\[
> \text{ui; vgroup [] ("test", [nentry #<pointer 0x1611f00> [] ("gain", 0.3, 0.0, 10.0, 0.01)])}
\]

In general, this data structure takes the form of a tree which corresponds to the hierarchical layout of the control groups and values in the Faust program. In this case, we just have one toplevel group containing a single gain parameter, which is represented as a Pure term containing the relevant information about the type, name, initial value, range and stepsize of the control, along with a double pointer which can be used to inspect and modify the control value. While it’s possible to access this information in a direct fashion, there’s also a faustui.pure module in the standard library which makes this easier. First we extract the mapping of control variable names to the corresponding double pointers as follows:

\[
> \text{using faustui;}
> \text{let ui = control_map $ controls ui; ui;}
(\"gain\" => #<pointer 0xd81820>)
\]

The result is a record value indexed by control names, thus the pointer which belongs to our gain control can now be obtained with ui!"gain". The faustui.pure module also provides convenience functions to inspect a control and change its value:
Let's rerun `compute` to get another block of samples from the same input data, using the new `gain` value:

```plaintext
> example::compute dsp n in out;
> out;
{32.0,34.0,36.0,38.0,40.0,42.0,44.0,46.0,48.0,50.0}
```

Faust also allows metadata to be attached to individual controls and control groups, which is available in the same form of a list of `key=>val` string pairs that we have seen already with the `meta` operation. This metadata is used to provide auxiliary information about a control to specific applications. It's completely up to the application how to interpret this metadata. Typical examples are style hints about GUI renderings of a control, or the assignment of external "MIDI" controllers. (MIDI is the “Musical Instruments Digital Interface”, a standardized hardware and software interface for electronic music instruments and other digital multimedia equipment.)

In our example these metadata lists are all empty. Control metadata is specified in a Faust program in the labels of the controls using the syntax `[key:val]`, please see the Faust documentation for details. For instance, if we'd like to assign MIDI controller 7 (usually the “volume controller” on MIDI keyboards) to our `gain` control, this might be done as follows:

```plaintext
gain = nentry("gain [midi:ctrl 7]", 0.3, 0, 10, 0.01);
```

After reloading the `dsp` and creating a new instance, this metadata is available in the `ui` structure and can be extracted with the `control_meta` function of the `faustui` module as follows:

```plaintext
> let dsp = test::newinit SR;
> let k,l,ui = example::info dsp;
> controls ui!0;
> nentry #<pointer 0x1c97070> ["midi"=>"ctrl 7"] ["gain",0.3,0.0,10.0,0.01]
> control_meta ans;
["midi"=>"ctrl 7"]
```

As you can see, all these steps are rather straightforward. Of course, in a real program we would probably run `compute` in a loop which reads some samples from an audio device or sound file, applies the `dsp`, and writes back the resulting samples to another audio device or file. We might also have to process MIDI controller input and change the control variables accordingly. This can all be done quite easily using the appropriate addon modules available on the Pure website.

We barely scratched the surface here, but it should be apparent that the programming techniques sketched out in this section open the door to the realm of sophisticated multimedia...
and signal processing applications. More Faust-related examples can be found in the Pure distribution. Also, have a look at the *pd-pure* and *pd-faust* packages to see how these facilities can be used in Pd modules written in Pure.

### 1.11 Interactive Usage

In interactive mode, the interpreter reads definitions and expressions and processes them as usual. You can use the `-i` option to force interactive mode when invoking the interpreter with some script files. Additional scripts can be loaded interactively using either a `using` declaration or the interactive `run` command (see the description of the `run` command below for the differences between these). Or you can just start typing away, entering your own definitions and expressions to be evaluated.

The input language is mostly the same as for source scripts, and hence individual definitions and expressions must be terminated with a semicolon before they are processed. For instance, here is a simple interaction which defines the factorial and then uses that definition in some evaluations. Input lines begin with “>”, which is the interpreter’s default command prompt:

```pure
> fact 1 = 1;
> fact n = n*fact (n-1) if n>1;
> let x = fact 10; x;
3628800
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

As indicated, in interactive mode the normal forms of toplevel expressions are printed after each expression is entered. This is also commonly known as the **read-eval-print loop**. Normal form expressions are usually printed in the same form as you’d enter them. However, there are a few special kinds of objects like anonymous closures, thunks (“lazy” values to be evaluated when needed) and pointers which don’t have a textual representation in the Pure syntax and will be printed in the format `#<object description>` by default. It is also possible to override the print representation of any kind of expression by means of the `__show__` function, see Pretty-Printing below for details.

A number of other special features of Pure’s command line interface are discussed in the following subsections.

#### 1.11.1 Command Syntax

Besides Pure definitions and expressions, the interpreter also understands a number of special interactive commands for performing basic maintenance tasks, such as loading source scripts, exiting and restarting the interpreter, changing the working directory, escaping to the shell, getting help and displaying definitions. In contrast to the normal input language, the command language is line-oriented; it consists of special command words to be typed at the beginning of an input line, which may be followed by some parameters as required by the command. The command language is intended solely for interactive purposes and thus doesn’t offer any programming facilities of its own. However, it can be extended with...
user-defined commands implemented as ordinary Pure functions; this is described in the User-Defined Commands section below.

In fact, as of Pure 0.56 the interpreter actually provides two slightly different command syntaxes, which we'll refer to as “default” and “escape mode”. The manual assumes that you’re running the interpreter in its traditional default mode where interactive commands are typed simply as they are shown in the following subsections, with the command word at the very beginning of the line. However, this mode has its pitfalls, especially for beginners. As most of the commands look just like ordinary identifiers, you may run into situations where the beginning of an expression or definition to be typed at the prompt can be mistaken for a command word. In such cases the default mode requires that you insert one or more spaces at the beginning of the line, so that the interpreter reads the line as normal Pure code. Unfortunately, it’s much too easy to forget this if you’re not familiar with the command language.

Therefore there is an alternative escape mode available which handles special command input more like some other popular programming language interpreters. In escape mode all interactive commands have to be escaped by prefixing them with a special character at the very beginning of the line. The command itself must follow the prefix character, without any intervening whitespace. Any line not prefixed with the prefix character will then be considered normal Pure code. This mode can be enabled with the --escape option, which takes the desired prefix character as an argument, or you can just set the PURE_ESCAPE variable in your environment to enable escape mode by default.

For example, to set the escape character to ‘:’ you’ll invoke the interpreter as follows:

```
$ pure --escape=:
```

Alternatively, you could also set the PURE_ESCAPE environment variable like this (using Bourne shell syntax):

```
$ export PURE_ESCAPE=:
```

Note that specifying the prefix character with the --escape option overrides the value of the environment variable, and only the initial character in the value of --escape or PURE_ESCAPE will be used. If the specified value is empty, the interpreter reverts to the default mode. The following prefix characters can be used: !$%&*:;<>@\|. Note that these all belong to 7 bit ASCII, and only some of the ASCII punctuation characters are permitted in order to prevent conflicts with ordinary Pure code. In any case, all of these characters can also occur in ordinary Pure code, so you should use a prefix that you aren’t likely to type at the beginning of a line in your usual coding style.

Many Pure programmers prefer escape mode, and in fact we recommend it for Pure novices even though it’s not the default (yet). Others may prefer default mode because it’s less effort to type. For the manual we stick to the default mode syntax. This means that if you’re running the interpreter in escape mode then you’ll have to do the necessary translation of the command syntax yourself. For instance, if the manual tells you to type the following command,
and you are using `'::` as the command prefix, then you will have to type this in escape mode instead:

```
> ::show foldl
```

Note that in this case `!' continues to serve as a shell escape:

```
> ! find . '*.pure'
```

This will not work, however, if you use `!' as your command prefix. In this case you will have to type two exclamation marks instead (the same caveat applies if you escape a shell command in the debugger, cf. Debugging):

```
> !! find . '*.pure'
```

This should be rather straightforward, so in the following we just use the default mode command syntax throughout without further notice.

---

**Note:** Escape mode only applies to the interactive command line. It doesn’t affect the evalcmd function in any way, so interactive commands in the string argument of evalcmd are always specified without the escape character prefix no matter which mode the interpreter is running in.

---

### 1.11.2 Online Help

Online help is available in the interpreter with the interactive `help` command, which gives you access to all the available documentation in html format; this includes the present manual, the *Pure Library Manual*, as well as all manuals of the addon modules available from the Pure website.

You need to have a html browser installed to make this work. By default, the `help` command uses `w3m`, but you can change this by setting either the `PURE_HELP` or the `BROWSER` environment variable accordingly.

When invoked without arguments, the `help` command displays an overview of the available documentation, from which you can follow the links to the provided manuals:

```
> help
```

(If the interpreter gives you an error message when you do this then you haven’t installed the documentation yet. The complete set of manuals is provided as a separate package at the Pure website, please see the Pure installation instructions for details.)

The `help` command also accepts a parameter which lets you specify a search term which is looked up in the global index, e.g.:

```
> help foldl
```
Besides Pure functions, macros, variables and constants described in the manual you can also look up program options and environment variables, e.g.:

> help -x
> help pure-gen -x
> help PURE_STACK

(Note that you can specify the program name to disambiguate between options for different utilities, such as the -x option which is accepted both by the Pure interpreter and the pure-gen program.)

If the search term doesn’t appear in the index, it is assumed to be a topic (a link target, usually a section title) in the Pure manual. Note that the docutils tools used to generate the html source of the Pure documentation mangle the section titles so that they are in lowercase and blanks are replaced with hyphens. So to look up the present section in this manual you’d have to type:

> help online-help

The help files are in html format and located in the docs subdirectory of the Pure library directory (i.e., /usr/local/lib/pure/docs by default). You can look up topics in any of the help files with a command like the following:

> help pure-gsl#matrices

Here pure-gsl is the basename of the help file (library path and .html suffix are supplied automatically), and matrices is a link target in that document. To just read the pure-gsl.html file without specifying a target, type the following:

> help pure-gsl#

(Note that just help pure-gsl won’t work, since it would look for a search term in the index or a topic in the Pure manual.)

Last but not least, you can also point the help browser to any html document (either a local file or some website) denoted by a proper URL, provided that your browser program can handle these. For instance:

> help file:mydoc.html#foo
> help https://agraef.github.io/pure-lang/

1.11.3 Interactive Commands

The following built-in commands are always understood by the interpreter. (In addition, you can define your own commands for frequently-used operations; see User-Defined Commands below.)

! command
  Shell escape.

break [symbol ...]
  Sets breakpoints on the given function or operator symbols. All symbols must be spec-
ified in fully qualified form, see the remarks below. If invoked without arguments, prints all currently defined breakpoints. This requires that the interpreter was invoked with the `-g` option to enable debugging support. See Debugging below for details.

**bt**

Prints a full backtrace of the call sequence of the most recent evaluation, if that evaluation ended with an unhandled exception. This requires that the interpreter was invoked with the `-g` option to enable debugging support. See Debugging below for details.

**cd dir**

Change the current working dir.

**clear [option ...] [symbol ...]**

Purge the definitions of the given symbols (functions, macros, constants or global variables). All symbols must be specified in fully qualified form, see the remarks below. If invoked as `clear ans`, clears the `ans` value (see Last Result below). When invoked without any arguments, `clear` purges all definitions at the current interactive “level” (after confirmation) and returns you to the previous level, if any. (It might be a good idea to first check your current definitions with `show` or back them up with `dump` before you do that.) The desired level can be specified with the `-t` option. See the description of the `save` command and Definition Levels below for further details. A description of the common options accepted by the `clear`, `dump` and `show` commands can be found in Specifying Symbol Selections below.

**del [-b|-m|-t] [symbol ...]**

Deletes breakpoints and tracepoints on the given function or operator symbols. If the `-b` option is specified then only breakpoints are deleted; similarly, `del -t` only deletes tracepoints. If none of these are specified then both breakpoints and tracepoints are deleted. All symbols must be specified in fully qualified form, see the remarks below. If invoked without non-option arguments, `del` clears all currently defined breakpoints and/or tracepoints (after confirmation); see Debugging below for details.

The `-m` option works similarly to `-t`, but deletes macro rather than function tracepoints, see the description of the `trace` command below.

**dump [-n filename] [option ...] [symbol ...]**

Dump a snapshot of the current function, macro, constant and variable definitions in Pure syntax to a text file. All symbols must be specified in fully qualified form, see the remarks below. This works similar to the `show` command (see below), but writes the definitions to a file. The default output file is `.pure` in the current directory, which is then reloaded automatically the next time the interpreter starts up in interactive mode in the same directory. This provides a quick-and-dirty way to save an interactive session and have it restored later, but note that this isn’t perfect. In particular, declarations of `extern` symbols won’t be saved unless they’re specified explicitly, and some objects like closures, thunks and pointers don’t have a textual representation from which they could be reconstructed. To handle these, you’ll probably have to prepare a corresponding `.purerc` file yourself, see Interactive Startup below.

A different filename can be specified with the `-n` option, which expects the name of the
script to be written in the next argument, e.g: dump -n myscript.pure. You can then edit that file and use it as a starting point for an ordinary script or a .purerc file, or you can just run the file with the run command (see below) to restore the definitions in a subsequent interpreter session.

**help [topic]**
Display online documentation. If a topic is given, it is looked up in the index. Alternatively, you can also specify a link target in any of the installed help files, or any other html document denoted by a proper URL. Please see Online Help above for details.

**ls [args]**
List files (shell ls command).

**mem**
Print current memory usage. This reports the number of expression cells currently in use by the program, along with the size of the freelist (the number of allocated but currently unused expression cells). Note that the actual size of the expression storage may be somewhat larger than this, since the runtime always allocates expression memory in bigger chunks. Also, this figure does not reflect other heap-allocated memory in use by the program, such as strings or malloc’ed pointers.

**override**
Enter “override” mode. This allows you to add equations “above” existing definitions in the source script, possibly overriding existing equations. See Definition Levels below for details.

**pwd**
Print the current working dir (shell pwd command).

**quit**
Exits the interpreter.

**run [-g|script]**
When invoked without arguments or with the -g option, run does a “cold” restart of the interpreter, with the scripts and options given on the interpreter’s original command line. If just -g is specified as the argument, the interpreter is run with debugging enabled. Otherwise the interpreter is invoked without debugging support. (This overrides the corresponding option from the interpreter’s command line.) This command provides a quick way to rerun the interpreter after changes in some of the loaded script files, or if you want to enable or disable debugging on the fly (which requires a restart of the interpreter). You’ll also lose any definitions that you entered interactively in the interpreter, so you may want to back them up with dump beforehand.

When invoked with a script name as argument, run loads the given script file and adds its definitions to the current environment. This works more or less like a using clause, but only searches for the script in the current directory and places the definitions in the script at the current temporary level, so that clear can be used to remove them again. Also note that namespace and pragma settings of scripts loaded with run stick around after loading the script. This allows you to quickly set up your environment by just running a script containing the necessary namespace declarations and compiler directives. (Alternatively, you can also use the interpreter’s startup files for that purpose,
save
Begin a new level of temporary definitions. A subsequent clear command (see above) will purge the definitions made since the most recent save command. See Definition Levels below for details.

show [option ...] [symbol ...]
Show the definitions of symbols in various formats. See The show Command below for details. All symbols must be specified in fully qualified form, see the remarks below. A description of the common options accepted by the clear, dump and show commands can be found in Specifying Symbol Selections below.

stats [-m] [on|off]
Enables (default) or disables “stats” mode, in which some statistics are printed after an expression has been evaluated. Invoking just stats or stats on only prints the cpu time in seconds for each evaluation. If the -m option is specified, memory usage is printed along with the cpu time, which indicates the maximum amount of expression memory (in terms of expression cells) used during the computation. Invoking stats off disables stats mode, while stats -m off just disables the printing of the memory usage statistics.

trace [-a] [-m] [-r] [-s] [symbol ...]
Sets tracepoints on the given function or operator symbols. Without the -m option, this works pretty much like the break command (see above) but only prints rule invocations and reductions without actually interrupting the evaluation; see Debugging below for details.

The -m option allows you to trace macro (rather than function) calls. If this option is specified, the compiler prints reduction sequences involving the given macro symbol, which is useful when debugging macros; see the Macros section for details and examples. Note that macro tracing works even if the interpreter was invoked without debugging mode.

If the -a option is specified, tracepoints are set on all global function or macro symbols, respectively (in this case the symbol arguments are ignored). This is convenient if you want to see any and all reductions performed in a computation.

Tracing can actually be performed in two different modes, recursive mode in which the trace is triggered by any of the active tracepoints and continues until the corresponding call is finished, or skip mode in which only calls by the active tracepoints are reported. The former is usually more helpful and is the default. The -s option allows you to switch to skip mode, while the -r option switches back to recursive mode.

Finally, if neither symbols nor any of the -a, -r and -s options are specified then the currently defined tracepoints are printed. Note that, as with the break command, existing tracepoints can be deleted with the del command (see above).

underride
Exits “override” mode. This returns you to the normal mode of operation, where new
equations are added “below” previous rules of an existing function. See Definition Levels below for details.

Commands that accept options generally also understand the -h (help) option which prints a brief summary of the command syntax and the available options.

Note that symbols (identifiers, operators etc.) must always be specified in fully qualified form. No form of namespace lookup is performed by commands like break, clear, show etc. Thus the specified symbols always work the same no matter what namespace and using namespace declarations are currently in effect.

Besides the commands listed above, the interpreter also provides some special commands for the benefit of other programs such as emacs driving the interpreter; currently these are completion_matches, help_matches and help_index. These aren’t supposed to be invoked directly by the user, although they may sometimes be useful to implement custom functionality, see User-Defined Commands.

1.11.4 Specifying Symbol Selections

The clear, dump and show commands all accept the following options for specifying a subset of symbols and definitions on which to operate. All symbols must be specified in fully qualified form. Options may be combined, thus, e.g., show -mft is the same as show -m -f -t. Some options specify optional numeric parameters; these must follow immediately behind the option character if present, as in -t0.

- **c** Select defined constants.
- **f** Select defined functions.
- **g** Indicates that the following symbols are actually shell glob patterns and that all matching symbols should be selected.
- **m** Select defined macros.
- **pflag** Select only private symbols if flag is nonzero (the default), otherwise (flag is zero) select only public symbols. If this option is omitted then both private and public symbols are selected.
- **tlevel** Select symbols and definitions at the given “level” of definitions and above. This is described in more detail below. Briefly, the executing program and all imported modules (including the prelude) are at level 0, while “temporary” definitions made interactively in the interpreter are at level 1 and above. Thus a level of 1 restricts the selection to all temporary definitions, whereas 0 indicates all definitions (i.e., everything, including the prelude). If level is omitted, it defaults to the current definitions level.
- **v** Select defined variables.
- **y** Select defined types.

In addition, the -h option prints a short help message describing all available options of the command at hand.
If none of the -c, -f, -m, -v and -y options are specified, then all kinds of symbols (constants, functions, macros, variables and types) are selected, otherwise only the specified categories will be considered.

A reasonable default is used if the -t option is omitted. By default, if no symbols are specified, only temporary definitions are considered, which corresponds to -t1. Otherwise the command applies to all corresponding definitions, no matter whether they belong to the executing program, the prelude, or some temporary level, which has the same effect as -t0. This default choice can be overridden by specifying the desired level explicitly.

As a special case, just clear (without any other options or symbol arguments) always backs out to the previous definitions level (instead of level #1). This is inconsistent with the rules set out above, but is implemented this way for convenience and backward compatibility. Thus, if you really want to delete all your temporary definitions, use clear -t1 instead. When used in this way, the clear command will only remove temporary definitions; if you need to remove definitions at level #0, you must specify those symbols explicitly.

Note that clear -g * will have pretty much the same disastrous consequences as the Unix command rm -rf *, so don’t do that. Also note that a macro or function symbol may well have defining equations at different levels, in which case a command like clear -tn foo might only affect some part of foo’s definition. The dump and show commands work analogously (albeit less destructively). See Definition Levels below for some examples.

### 1.11.5 The show Command

The show command can be used to obtain information about defined symbols in various formats. Besides the common selection options discussed above, this command recognizes the following additional options for specifying the content to be listed and the format to use.

- **-a** Disassembles pattern matching automata. Works like the -v4 option of the interpreter.
- **-d** Disassembles LLVM IR, showing the generated LLVM assembler code of a function. Works like the -v8 option of the interpreter.
- **-e** Annotate printed definitions with lexical environment information (de Bruijn indices, subterm paths). Works like the -v2 option of the interpreter.
- **-l** Long format, prints definitions along with the summary symbol information. This implies -s.
- **-s** Summary format, print just summary information about listed symbols.

Symbols are always listed in lexicographic order. Note that some of the options (in particular, -a and -d) may produce excessive amounts of information. By setting the PURE_MORE environment variable, you can specify a shell command to be used for paging, usually more or less.

For instance, to list all temporary definitions made in an interactive session, simply say:

```
> show
```

You can also list a specific symbol, no matter whether it comes from the interactive command line, the executing script or the prelude:
> show foldl
foldl f a x::matrix = foldl f a (list x);
foldl f a s::string = foldl f a (chars s);
foldl f a [] = a;
foldl f a (x:xs) = foldl f (f a x) xs;

Wildcards can be used with the -g option, which is useful if you want to print an entire family of related functions, e.g.:

> show -g foldl*
foldl f a x::matrix = foldl f a (list x);
foldl f a s::string = foldl f a (chars s);
foldl f a [] = a;
foldl f a (x:xs) = foldl f (f a x) xs;
foldl1 f x::matrix = foldl1 f (list x);
foldl1 f s::string = foldl1 f (chars s);
foldl1 f (x:xs) = foldl f x xs;

Or you can just specify multiple symbols as follows (this also works with multiple glob patterns when you add the -g option):

> show min max
max x y = if x>=y then x else y;
min x y = if x<=y then x else y;

You can also select symbols by category. E.g., the following command shows summary information about all the variable symbols along with their current values (using the “long” format):

> show -lvg *
argc var argc = 0;
argv var argv = [];
compiling var compiling = 0;
sysinfo var sysinfo = "x86_64-unknown-linux-gnu";
version var version = "0.68";
5 variables

Or you can list just private symbols of the namespace foo, as follows:

> show -pg foo::*
The following command will list each and every symbol that’s currently defined (instead of -g * you can also use the -t0 option):

> show -g *

This usually produces a lot of output and is rarely needed, unless you’d like to browse through an entire program including all library imports. (In that case you might consider to use the dump command instead, which writes the definitions to a file which can then be loaded into a text editor for easier viewing. This may occasionally be useful for debugging purposes.)
The `show` command also has the following alternate forms which are used for special purposes:

- **show interface** lists the actual *type* rules for an interface type. This is useful if you want to verify which patterns will be matched by an interface type, see Interface Types for details. For instance:

```plaintext
> interface stack with
  > push xs::stack x;
  > pop xs::stack;
  > top xs::stack;
> end;
> push xs[] x |
> push xs[@(____)] x = x:xs;
> pop (x:xs) = xs;
> top (x:xs) = x;
> show interface stack
type stack xs@[____];
> pop [] = throw "empty stack";
> top [] = throw "empty stack";
> show interface stack
type stack xs[];
type stack xs[@____];
```

- **show namespace** lists the current and search namespaces, while **show namespaces** lists all declared namespaces. These come in handy if you have forgotten what namespaces are currently active and which other namespaces are available in your program. For instance:

```plaintext
> show namespace
> show namespaces
namespace C;
namespace matrix;
> using namespace C;
> namespace my;
> show namespace
namespace my;
using namespace C;
```

### 1.11.6 Definition Levels

To help with incremental development, the interpreter offers some commands to manipulate the current set of definitions interactively. To these ends, definitions are organized into different subsets called *levels*. As already mentioned, the prelude, as well as other source programs specified when invoking the interpreter, are always at level 0, while the interactive environment starts at level 1. Each `save` command introduces a new temporary level, and each subsequent `clear` command (without any arguments) “pops” the definitions on the current level and returns you to the previous one (if any). This gives you a “stack” of temporary environments which enables you to “plug and play” in a (more or less) safe fashion, without affecting the rest of your program.
For all practical purposes, this stack is unlimited, so that you can create as many levels as you like. However, this facility also has its limitations. The interpreter doesn’t really keep a full history of everything you entered interactively, it only records the level a variable, constant, and function or macro rule belongs to so that the corresponding definitions can be removed again when the level is popped. On the other hand, intermediate changes in variable values are not recorded anywhere and cannot be undone. Moreover, global declarations (which encompasses using clauses, extern declarations and special symbol declarations) always apply to all levels, so they can’t be undone either.

That said, the temporary levels can still be pretty useful when you’re playing around with the interpreter. Here’s a little example which shows how to use clear to quickly get rid of a definition that you entered interactively:

```plaintext
> foo (x:xs) = x+foo xs;
> foo [] = 0;
> show
foo (x:xs) = x+foo xs;
foo [] = 0;
> foo (1..10);
55
> clear
This will clear all temporary definitions at level #1.
Continue (y/n)? y
> show
> foo (1..10);
foo [1,2,3,4,5,6,7,8,9,10]
```

We’ve seen already that normally, if you enter a sequence of equations, they will be recorded in the order in which they were written. However, it is also possible to override definitions in lower levels with the override command:

```plaintext
> foo (x:xs) = x+foo xs;
> foo [] = 0;
> show
foo (x:xs) = x+foo xs;
foo [] = 0;
> foo (1..10);
55
> override
> foo (x:xs) = x+foo xs;
> show
foo (x:xs) = x+foo xs;
foo (x:xs) = x+foo xs;
foo [] = 0;
> foo (1..10);
warning: rule never reduced: foo (x:xs) = x+foo xs;
0
```

Note that the equation `foo (x:xs) = x+foo xs` was inserted before the previous rule `foo (x:xs) = x+foo xs`, which is at level #1. (The latter equation is now “shadowed” by the
rule we just entered, hence the compiler warns us that this rule can’t be reduced any more.)

Even in override mode, new definitions will be added after other definitions at the current level. This allows us to just continue adding more high-priority definitions overriding lower-priority ones:

> foo [] = 1;
> show
foo (x:xs) = x+foo xs;
foo [] = 1;
foo (x:xs) = x+foo xs;
foo [] = 0;
> foo (1..10);
warning: rule never reduced: foo (x:xs) = x+foo xs;
warning: rule never reduced: foo [] = 0;
3628800

Again, the new equation was inserted above the existing lower-priority rules, but below our previous equation foo (x:xs) = x*foo xs entered at the same level. As you can see, we have now effectively replaced our original definition of foo with a version that calculates list products instead of sums, but of course we can easily go back one level to restore the previous definition:

> clear
This will clear all temporary definitions at level #2.
Continue (y/n}? y
clear: now at temporary definitions level #1
clear: override mode is on
> show
foo (x:xs) = x+foo xs;
foo [] = 0;
> foo (1..10);
55

Note that clear reminded us that override mode is still enabled (save will do the same if override mode is on while pushing a new definitions level). To turn it off again, use the underride command. This will revert to the normal behaviour of adding new equations below existing ones:

> underride

It’s also possible to use clear to back out multiple levels at once, if you specify the target level to be cleared with the -t option. For instance:

> save
save: now at temporary definitions level #2
> let bar = 99;
> show
let bar = 99;
foo (x:xs) = x+foo xs;
foo [] = 0;
> // this scraps all our scribbings!
> clear -t1

1.11.6 Definition Levels
This will clear all temporary definitions at level #1 and above.
Continue (y/n)? y

The facilities described above are also available to Pure programs, as the save and clear commands can also be executed under program control using the \texttt{evalcmd} primitive. Conversely, the library provides its own functions for inspecting and manipulating the source program, which may also be useful in custom command definitions; see the \textit{Pure Library Manual} for details.

1.11.7 Debugging

The interpreter provides a simple but reasonably convenient symbolic debugging facility when running interactively. To make this work, you have to specify the \texttt{-g} option when invoking the interpreter (\texttt{pure -g}). If you’re already at the interpreter’s command line, you can also use the \texttt{run -g} command to enable the debugger. The \texttt{-g} option disables tail call optimization (see Stack Size and Tail Recursion) to make it easier to debug programs. It also causes special debugging code to be generated which will make your program run much slower. Therefore the \texttt{-g} option should only be used if you actually need the debugger.

One common use of the debugger is “post mortem” debugging after an evaluation ended with an unhandled exception. In such a case, the \texttt{bt} command of the interpreter prints a backtrace of the call sequence which caused the exception. Note that this only works if debugging mode was enabled. For instance:

\begin{verbatim}
> [1,2]!3;
<stdin>, line 2: unhandled exception 'out_of_bounds' while evaluating '[1,2]!3'
> bt
[1] (!): (x:xs)!n::\texttt{int} = xs!(n-1) \texttt{if} n>0;
  n = 3; x = 1; xs = [2]
[2] (!): (x:xs)!n::\texttt{int} = xs!(n-1) \texttt{if} n>0;
  n = 2; x = 2; xs = []
[3] (!): []!n::\texttt{int} = throw out_of_bounds;
  n = 1
>> [4] throw: \texttt{extern void pure_throw(expr*)} = throw;
  x1 = out_of_bounds
\end{verbatim}

The last call, which is also marked with the \texttt{>>} symbol, is the call that raised the exception. The format is similar to the \texttt{p} command of the debugger, see below, but \texttt{bt} always prints a full backtrace. (As with the \texttt{show} command of the debugger, you can set the \texttt{PURE_MORE} environment variable to pipe the output through the corresponding command, or use \texttt{evalcmd} to capture the output of \texttt{bt} in a string.)

The debugger can also be used interactively. To these ends, you can set breakpoints on functions with the \texttt{break} command. The debugger then gets invoked as soon as a rule for one of the given functions is executed. Example:
> fact n::int = if n>0 then n*fact (n-1) else 1;
> break fact
> fact 1;
** [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 1
  (Type 'h' for help.) :
** [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 0 :
++ [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 0
    --> 1
** [2] (*): x::int+y::int = x*y;
  x = 1; y = 1 :
++ [2] (*): x::int+y::int = x*y;
  x = 1; y = 1
    --> 1
++ [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 1
    --> 1
1

Lines beginning with ** indicate that the evaluation was interrupted to show the rule (or external) which is currently being considered, along with the current depth of the call stack, the invoked function and the values of parameters and other local variables in the current lexical environment. In contrast, the prefix ++ denotes reductions which were actually performed during the evaluation and the results that were returned by the function call (printed as --> return value).

Sometimes you might also see funny symbols like #<closure>, #<case> or #<when> instead of the function name. These indicate lambdas and the special variable-binding environments, which are all implemented as anonymous closures in Pure. Also note that the debugger doesn’t know about the argument names of external functions (which are optional in Pure and not recorded anywhere), so it will display the generic names x1, x2 etc. instead.

At the debugger prompt ‘:’ you can enter various special debugger commands, or just keep on hitting the carriage return key to walk through an evaluation step by step, as we did in the example above. (Command line editing works as usual at the debugger prompt, if it is enabled.) The usual commands are provided to walk through an evaluation, print and navigate the call stack, step over the current call, or continue the evaluation unattended until you hit another breakpoint. If you know other source level debuggers like gdb then you should feel right at home. You can type h at the debugger prompt to print the following list:

: h
Debugger commands:
  a    auto: step through the entire program, run unattended
  c [f] continue until next breakpoint, or given function f
  h    help: print this list

1.11.7 Debugging
n  next step: step over reduction
p  [n] print rule stack (n = number of frames)
r  run: finish evaluation without debugger
s  single step: step into reduction
t, b move to the top or bottom of the rule stack
u, d move up or down one level in the rule stack
x  exit the interpreter (after confirmation)
.  reprint current rule
!  cmd execute interpreter command
?  expr evaluate expression
<cr> single step (same as 's')
<eof> step through program, run unattended (same as 'a')

Note: If you specified an --escape prefix other than ‘!’ (cf. Command Syntax), that prefix will be used to execute interpreter commands instead, see below. The help message will tell you which command prefix is in effect.

The command syntax is very simple. Besides the commands listed above you can also enter comment lines (// comment text) which will just be ignored. Extra arguments on commands which don’t expect any will generally be ignored as well. The single letter commands all have to be separated from any additional parameters with whitespace, whereas the ‘!’, ‘?’ and ‘.’ commands count as word delimiters and can thus be followed immediately by an argument. For convenience, the ‘?’ command can also be omitted if the expression to be evaluated doesn’t start with a single letter or one of the special punctuation commands.

The debugger can be exited or suspended in the following ways:

- You can type c to continue the evaluation until the next breakpoint, or c foo in order to proceed until the debugger hits an invocation of the function foo.
- You can type r to run the rest of the evaluation without the debugger.
- The a (“auto”) command single-steps through the rest of the evaluation, running unattended. This command can also be entered by just hitting the end-of-file key (Ctrl-d on Unix systems) at the debugger prompt.
- You can also type x to exit from the debugger and the interpreter immediately (after confirmation).

In addition, you can use the ! command (or whatever command prefix has been set with the --escape option) to run any interpreter command while in the debugger. For instance:

: !ls

This is particularly useful to invoke the break and del commands to change breakpoints. Note that you can actually escape any valid input to the interpreter that way, not just the special interactive commands. However, you shouldn’t try to modify the program while you’re debugging it. This may work in some cases, but will have nasty consequences if you happen to change a function which is currently being executed.

The interpreter’s shell escape can also be used from the debugger. In default mode or when
using ! as the --escape prefix, you’ll have to escape shell commands with !!, otherwise a single ! suffices.

At the debugger prompt, you can use the u ("up"), d ("down"), t ("top") and b ("bottom") commands to move around on the current call stack. The p command prints a range of the call stack centered around the currently selected stack frame, which is indicated with the >> tag, whereas ** denotes the current bottom of the stack (which is the rule to be executed with the single step command). The p command can also be followed by a numeric argument which indicates the number of stack frames to be printed (this will then become the default for subsequent invocations of p). The n command steps over the call selected with the stack navigation commands. For instance:

```plaintext
> fact 3;
** [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 3
: c *
** [4] (*): x::int*y::int = x*y;
    x = 1; y = 1
: p
    [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 3
    [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 2
    [3] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 1
** [4] (*): x::int*y::int = x*y;
    x = 1; y = 1
: u
>> [3] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 1
: u
>> [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 2
: p
    [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 3
    >> [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 2
    [3] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
        n = 1
** [4] (*): x::int*y::int = x*y;
    x = 1; y = 1
: n
  ++ [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
          n = 2
  --> 2
** [2] (*): x::int*y::int = x*y;
    x = 3; y = 2
: u
>> [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 2
```

If you ever get lost, you can reprint the current rule with the ‘.’ command:
Another useful feature is the ? command which lets you evaluate any Pure expression, with the local variables of the current rule bound to their corresponding values. Like the n command, ? applies to the current stack frame as selected with the stack navigation commands. The expression must be entered on a single line, and the trailing semicolon is optional. For instance:

```pure
> fact 3;
** [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 3
: c *
** [4] (*): x::int+y::int = x*y;
 x = 1; y = 1
: ?x+y
 2
: u
>> [3] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 1
: n>0, fact n
1,1
```

A third use of the debugger is to trace function calls. For that the interpreter provides the trace command which works similarly to break, but sets so-called “tracepoints” which only print rule invocations and reductions instead of actually interrupting the evaluation. For instance, assuming the same example as above, let’s first remove the breakpoint on fact (using the del command) and then set it as a tracepoint instead:

```pure
> del fact
> trace fact
> fact 1;
** [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 1
** [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 0
++ [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 0
 --> 1
** [2] (*): x::int+y::int = x*y;
 x = 1; y = 1
++ [2] (*): x::int+y::int = x*y;
 x = 1; y = 1
 --> 1
++ [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
 n = 1
 --> 1
1
```

The break and trace commands can also be used in concert if you want to debug some functions while only tracing others.
Note that the \texttt{trace} command can actually be run in two different modes: \textit{recursive} mode in which the trace is triggered by any of the active tracepoints and continues until the corresponding call is finished, or \textit{skip} mode in which only calls by the active tracepoints are reported. The former is the default and is often preferable, because it gives you a complete transcript of the reductions performed during a function call.

If you don’t need that much detail, you can also switch to skip mode by invoking the \texttt{trace} command with the \texttt{-s} option. This allows you to see a quick summary of the computation which only shows reductions by rules directly involving the active tracepoints. For instance:

\begin{verbatim}
> trace -s
> fact 1;
** [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 1
** [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
  n = 0
++ [2] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 0
      --> 1
++ [1] fact: fact n::int = if n>0 then n*fact (n-1) else 1;
    n = 1
      --> 1
1
\end{verbatim}

Moreover, the \texttt{trace} command can also be invoked with the \texttt{-a} option to trace all function calls, which is convenient to quickly obtain a full transcript of a reduction sequence. The same options also work in an analogous fashion with macro calls, see the Macros section for some examples.

The current sets of breakpoints and tracepoints can be changed with the \texttt{break}, \texttt{trace} and \texttt{del} commands, as shown above, and just \texttt{break} or \texttt{trace} without any arguments lists the currently defined breakpoints or tracepoints, respectively. Please see Interactive Commands above for details. Also note that these are really interpreter commands, so to invoke them in the debugger you have to escape them with the \texttt{!} command (or whatever other \texttt{- -escape} prefix you specified).

The debugger can also be triggered programmatically with the built-in parameter-less functions \texttt{__break__} and \texttt{__trace__}. This gives you much better control over the precise location and the conditions under which the debugger should be invoked. Just place a call to \texttt{__break__} or \texttt{__trace__} near the point where you’d like to start debugging or tracing; this can be done either with the sequencing operator \texttt{\$\$} or with a \texttt{when} clause. The debugger will then be invoked at the next opportunity (usually when a function is called or a reduction is completed). For instance:

\begin{verbatim}
> fact n::int = if n>0 then __break__ $$ n*fact (n-1) else 1;
> fact 10;
++ [2] __break__: extern void pure_break() = __break__;
    --> ()
++ [2] fact: fact n::int = if n>0 then __break__ $$n*fact (n-1) else 1;
    n = 9
:  
\end{verbatim}
Here the debugger is invoked right after the call to `__break__`, when the `n*fact (n-1)` expression in the `then` branch is about to be evaluated. The debugger thus stops at the recursive invocation of `fact 9`. Tracing works in a similar fashion, using `__trace__` in lieu of `__break__`, and continues until the current stack frame is exited. One major advantage of this method is that it is possible to invoke `__break__` or `__trace__` only under certain conditions, so that you can focus on interesting “events” during evaluation, which can make debugging much less tedious. In our example, in order to stop when `n` becomes 1, we might invoke `__break__` as follows:

```plaintext
> fact n::int = if n>0 then n>1||__break__ $$ n*fact (n-1) else 1;
> fact 3;
++ [4] __break__: extern void pure_break() = __break__;
--> ()
```

Another convenience for interactive usage is the `ans` function, which retrieves the most recent result printed in interactive mode. For instance:

```plaintext
> fact n = if n<=1 then 1 else n*fact (n-1);
> map fact (1..10);
[1,2,6,24,120,720,5040,40320,362880,3628800]
> scanl (+) 0 ans;
[0,1,3,9,33,153,873,5913,46233,4037913]
```

Note that `ans` is just an ordinary function, defined in the prelude, not a special command. However, there is a special `clear ans` command which purges the `ans` value. This is useful, e.g., if you got a huge result which you want to erase from memory before starting the next computation.

```plaintext
> clear ans
> ans;
ans
```

### 1.11.9 Pretty-Printing

The interpreter provides the following “hook” to override the print representations of expressions. This works in a fashion similar to Haskell’s `show` function.
The programmer may define this function to supply custom print representations for
certain expressions.

__show__ is just an ordinary Pure function expected to return a string with the desired cus-
tom representation of a normal form value given as the function’s single argument. The
interpreter prints the strings returned by __show__ just as they are. It will not check whether
they conform to Pure syntax and/or semantics, or modify them in any way. Also, the library
doesn’t define this function anywhere, so you are free to add any rules that you want.

Custom print representations are most useful for interactive purposes, if you’re not happy
with the default print syntax of some kinds of objects. One particularly useful application of
__show__ is to change the format of numeric values. Here are some examples:

```
> using system;
> __show__ x::double = sprintf "%0.6f" x;
> 1/7;
 0.142857
> __show__ x::int = sprintf "0x%x" x;
> 1786;
0x6fa
> using math;
> __show__ (x::double :+: y::double) = sprintf "%0.6f+%0.6fi" (x,y);
> cis (-pi/2);
 0.000000+-1.000000i
```

The prelude function `str`, which returns the print representation of any Pure expression,
calls __show__ as well:

```
> str (1/7);
"0.142857"
```

Conversely, you can call the `str` function from __show__, but in this case it always returns
the default representation of an expression. This prevents the expression printer from going
recursive, and allows you to define your custom representation in terms of the default one.
E.g., the following rule removes the L suffixes from bigint values:

```
> __show__ x::bigint = init (str x);
> fact n = foldl (*) 1L (1..n);
> fact 30;
26525285981219105863630848000000
```

Of course, your definition of __show__ can also call __show__ itself recursively to determine
the custom representation of an object.

One case which needs special consideration are thunks (futures). The printer will never use
__show__ for those, to prevent them from being forced inadvertently. In fact, you can use
__show__ to define custom representations for thunks, but only in the context of a rule for
other kinds of objects, such as lists. For instance:

```
> nonfix ...;
> __show__ (x:xs) = str (x:...) if thunkp xs;
```
Another case which needs special consideration are numeric matrices. For efficiency, the expression printer will always use the default representation for these, unless you override the representation of the matrix as a whole. E.g., the following rule for double matrices mimics Octave's default output format (for the sake of simplicity, this isn't perfect, but you get the idea):

```plaintext
> __show__ x::matrix =
>   strcat [printd j (x!(i,j))|i=0..n-1; j=0..m-1] + "\n"
> with printd 0 = sprintf "%10.5f"; printd _ = sprintf "%10.5f" end
> when n,m = dim x end if dmatrixp x;
>   {1.0; 1/2; 1/3, 4.0};
>     1.00000  0.50000
>     0.33333  4.00000
```

Finally, by just purging the definition of the `__show__` function you can easily go back to the standard print syntax:

```plaintext
> clear __show__
> 1/7; 1786; cis (-pi/2);
> 0.142857142857143
> 1786
> 6.12303176911189e-17+-1.0
```

Note that if you have a set of definitions for the `__show__` function which should always be loaded at startup, you can put them into the interpreter’s interactive startup files, see Interactive Startup below.

### 1.11.10 User-Defined Commands

It is possible to extend the interpreter with your own interactive commands. To these ends, all you have to do is provide some corresponding public function definitions in the special `__cmd__` namespace (cf. Namespaces). These definitions are typically placed in one of the interpreter’s startup files (see Interactive Startup below) so that they are always available when running the interpreter interactively.

A command function is invoked with one string argument which contains the rest of the command line (with leading and trailing whitespace stripped off). It may return a string result which is printed on standard output (appending a newline if needed). Thus a simple command which just prints its arguments as is can be implemented as follows:

```plaintext
> namespace __cmd__;
> echo s = s;
> echo Hello, world!
Hello, world!
```

You can split arguments and do any required processing of the arguments with the usual string processing functions. For instance, let’s change our `echo` command so that it prints each whitespace-delimited token on a line of its own:
A command function may in fact return any kind of value. However, only string results are printed by the interpreter, other results are silently ignored. Thus we might implement the echo command in a direct fashion, using the C `puts` function:

```
> clear __cmd__::echo
> private extern int
>     puts(char*);
> echo s = puts s;
> echo Hello, world!
Hello, world!
```

Note that we declared `puts` as a private symbol here. In general, the interpreter only exposes public functions in the `__cmd__` namespace as commands, private symbols are hidden. On the other hand, we might also just expose the external function `puts` itself under the (public) alias `echo`, so here's yet another possible implementation of the echo command:

```
> clear __cmd__::echo
> extern int
>     puts(char*) = echo;
```

Instead of returning a result, a command function may also throw an exception. If the exception value is a string, it will be printed as an error message on standard error, using the same format as the built-in commands:

```
> error s = throw s;
> error Hello, world!
error: Hello, world!
```

You can also override a built-in command in order to provide custom functionality. In this case, the original builtin can still be executed by escaping the command name with a leading `^`. The same syntax works with the `evalcmd` function, so that a custom command can be defined in terms of the builtin that it replaces. E.g., if we always want to invoke the `ls` command with the `-l` option, we can redefine the `ls` command as follows:

```
> ls examples/*.c
examples/poor.c  examples/sort.c
> ls s = evalcmd $ '^ls -l' +s;
> ls examples/*.c
-rw-r--r-- 1 ag users 1883 2011-01-07 16:35 examples/poor.c
-rw-r--r-- 1 ag users 3885 2011-01-07 16:35 examples/sort.c
```

(Note that since we entered the definition of the `ls` function interactively, we need to escape the second input line above with leading whitespace, so that it's not mistaken for an invoca-
tion of the built-in `ls` command. This isn’t necessary if you’re using the alternative “escape” command syntax described in Command Syntax.)

To do more interesting things, you should take a look at the reflection capabilities discussed in the Macros section, which open up endless possibilities for commands to inspect and manipulate the running program in an interactive fashion. For instance, let’s define a variation of the built-in `clear` command which allows us to delete a specific rule rather than an entire function definition:

```plaintext
namespace __cmd__;

clr s = case val $("'(0 with "+s+" end)" of
    '(0 __with__ [r]) = del_fundef r;
  _ = throw "bad rule syntax";
end;

Note that we employ a little trick here to have `val` do all the hard work of parsing the rule specified as argument to the command, in order to translate the Pure rule syntax to the special meta representation used by `del_fundef`. The following example shows our `clr` command in action:

```plaintext
> namespace;
> fact n = 1 if n<=0;
> = n*fact (n-1) otherwise;
> show fact

```
fact n = 1 if n<=0;
fact n = n*fact (n-1);
```

```plaintext
> clr fact n = 1 if n<=0;
> show fact

```
fact n = n*fact (n-1);
```

Here’s another useful command `apropos` which quickly summarizes the information available on a given symbol (as reported by the `show` and `help_index` commands):

```plaintext
namespace __cmd__;
apropos s = case catmap descr split "|n| $ evalcmd $ "show -s "+s of
    [] = throw $ "undefined symbol '"+s+"'";
    info = s+ is a "+join " and a " info+". \Type 'show "+s+"' for more information."+
    (if null (evalcmd $ "help_index "+s) then " else
        "Documentation for this symbol is available. Type 'help "+s+"'.");
end with
descr info = case [x | x = split " " info; ~null x] of
t::c:: = [symtypes!c] if s==t when
    symtypes = {"fun"=>"function","mac"=>"macro","var"=>"variable","cst"=>"constant"};
  _ = [];
end;
end;
```

This command can be used as follows:
More examples can be found in the sample.purerc file distributed with the Pure interpreter.

### 1.11.11 Interactive Startup

In interactive mode, the interpreter runs some additional scripts at startup, after loading the prelude and the scripts specified on the command line. This lets you tailor the interactive environment to your liking.

The interpreter first looks for a .purerc file in the user’s home directory (as given by the HOME environment variable) and then for a .purerc file in the current working directory. These are just ordinary Pure scripts which may contain any additional definitions (including command definitions, as described in the previous section) that you need. The .purerc file in the home directory is for global definitions which should always be available when running interactively, while the .purerc file in the current directory can be used for project-specific definitions.

Finally, you can also have a .pure initialization file in the current directory, which is usually created with the dump command (see above). This file is loaded after the .purerc files if it is present.

The interpreter processes all these files in the same way as with the run command (see Interactive Commands above). When invoking the interpreter, you can specify the --norc option on the command line if you wish to skip these initializations.

### 1.12 Batch Compilation

The interpreter’s -c option provides a means to quickly turn Pure scripts into standalone executables. The compiled executable is essentially a static snapshot of your program which is executed on the “bare metal”, without a hosting interpreter and with just a minimal runtime system. This considerably reduces startup times, but also implies some limitations (mostly related to meta-programming capabilities) which will be discussed in the following subsection, where we give a detailed account on the batch compilation process.

#### 1.12.1 Compile Time Versus Run Time

The batch compiler processes most of the script at compile time as usual. The only exception are plain toplevel expressions which are not executed during batch compilation, but of
course they are compiled and become part of the output code. Your program will normally
have to include at least one of these so that it does something useful. That is, the toplevel
expressions play the role of the “main program” in your script. They are best placed after all
the function and variable definitions, at the end of your program.

All other toplevel items are executed at compile time as usual. This includes constant and
variable definitions, which might seem a bit unusual, but can’t be avoided in a highly dy-
namic language like Pure (recall that even constants can be defined by evaluating arbitrary
expressions in Pure, and using eval a program can easily modify itself in even more un-
foreseeable ways). It also paves the way for the powerful programming technique of partial
evaluation (more about that later).

Thus it is important to keep in mind that if const and let bindings involve any code to
be executed, that code will be run also during batch compilation. What this means is that
permanent side-effects such as creating, writing or removing files should be avoided in these
definitions; reading permanent storage in order to initialize constants and variables should
be fine, though. Other side-effects should be confined to the toplevel expressions making up
your main program. (The compiler has no way of checking these policies, so they are the
programmer’s responsibility.)

In the case of const, the code needed to construct these values will normally be run only
during batch compilation and the resulting values are then either inlined in other definitions
or stored as read-only variables, see Constant Definitions for details. In contrast, the code
for let-bound variables will actually be executed twice, once during batch compilation, and
then again when the compiled program runs.

---

Note: There’s one corner case in which const is treated pretty much the same as let, namely
if a constant involves run time data such as pointers and closures. In such cases the constant
value has to be recomputed at run time and effectively becomes a (read-only) variable. (The
same applies if the --noconst option is used to force computation of constant values at run
time, see Options Affecting Code Size.)

The batch compiler always reorders the output code so that all toplevel expressions and let
bindings are evaluated after all functions have been defined. This is done to reduce the size
of the output executable, so that there’s only a single snapshot of each function which will
be used by all toplevel expressions and global variable definitions invoking the function.
Therefore you should avoid code like the following, which changes the function foo on the
fly between invocations:

```pure
let x = foo 99;
foo x = x+1;
let y = foo 99;
```

Last but not least, some parts of Pure’s meta-programming capabilities and other compile
time features are disabled in batch-compiled programs:

- The eval function can only be used to evaluate plain toplevel expressions. You can
define local functions and variables in with and when clauses inside an expression, but
you can’t use eval to define new global variables and functions. In other words, any-
thing which changes the executing program is “verboten”. Moreover, the introspective capabilities provided by `evalcmd` and similar operations (discussed under Reflection in the Macros section) are all disabled. If you need any of these capabilities at run time, you have to run your program with the interpreter.

- Constant and macro definitions, being compile time features, aren’t available in the compiled program. If you need to use these with `eval` at run time, you have to provide them through variable and function definitions instead. Also, the compiler usually strips unused functions from the output code, so that only functions which are actually called somewhere in the static program text are available to `eval`. (The `-u` option and the `--required` pragma can be used to avoid this, see Options Affecting Code Size below.)

What this boils down to is that in the batch-compiled program you will have to avoid anything which requires the compile time or interactive facilities of the interpreter. These restrictions only apply at run time, of course. During batch compilation the program is being executed by the interpreter, so you can use `eval` and `evalcmd` in any desired way. You just need to make sure that the corresponding code actually gets executed at compile time (remember that plain toplevel expressions aren’t). This can be done most conveniently by wrapping it up in a `const` or `let` construct, omitting the left-hand side (cf. Simple Rules):

```Pure
const eval "fancy compile time code goes here";
```

The same approach works with the other inspection operations discussed in Reflection, and also comes in handy if external C code requires initialization at compile time. In some cases it may be necessary to execute the same code both at compile and at run time, which can be achieved by using `let` in lieu of `const`.

Most kinds of scripts will work fine when batch-compiled, using the tricks we discussed above to work around the little kinks and limitations. For the few scripts which actually need the full dynamic capabilities of Pure you’ll just have to run the script with the interpreter, which shouldn’t usually be a big impediment either. Once the JIT has done its thing the “interpreted” script will run every bit as fast as the “compiled” one, since in fact both are compiled (only at different times) to exactly the same code!

### 1.12.2 Example

For the sake of a concrete example, consider the following little script:

```Pure
using system;

fact n = if n>0 then n*fact (n-1) else 1;

main n = do puts ["Hello, world!", str (map fact (1..n))];

if argc<=1 then () else main (sscanf (argv!1) "%d");
```

When invoked from the command line, with the number `n` as the first parameter, this program will print the string “Hello, world!” and the list of the first `n` factorials:
Note the condition on `argc` in the last line of the script. This prevents the program from producing an exception if no command line parameters are specified, so that the program can also be run interactively:

```plaintext
$ pure -i -q hello.pure
> main 10;
Hello, world!
[1,2,6,24,120,720,5040,40320,362880,3628800]
()
> quit
```

To turn the script into an executable, we just invoke the Pure interpreter with the `-c` option, using the `-o` option to specify the desired output file name:

```plaintext
$ pure -c hello.pure -o hello
$ ./hello 10
Hello, world!
[1,2,6,24,120,720,5040,40320,362880,3628800]
```

Next suppose that we’d like to supply the value `n` at compile rather than run time. This is what partial evaluation is all about. In Pure we can just turn the value passed to the `main` function into a compile time constant as follows:

```plaintext
const n = if argc>1 then sscanf (argv!1) "%d" else 10;
```

(Note that we provide 10 as a default if `n` isn’t specified on the command line.)

Our program now looks as follows:

```plaintext
using system;

fact n = if n>0 then n*fact (n-1) else 1;

main n = do puts ["Hello, world!", str (map fact (1..n))];

const n = if argc>1 then sscanf (argv!1) "%d" else 10;
main n;
```

This script “specializes” `n` to the first (compile time) parameter when being batch-compiled, and it still works as before when we run it through the interpreter in both batch and interactive mode, too:

```plaintext
$ pure -i -q hello.pure
Hello, world!
[1,2,6,24,120,720,5040,40320,362880,3628800]
> main 5;
Hello, world!
[1,2,6,24,120]
```
Finally, there’s also a compile time check which comes in handy if we want to execute different code depending on whether a script is batch-compiled or not; see Conditional Compilation. We might employ this as follows, replacing the last line of the script with this:

```plaintext
#! --if compiled
if argc>1 then main (sscanf (argv!1) "%d") else main n;
#! --else
if argc>1 then main n else puts "Try 'main n' where n is a number.;
#! --endif
```

The code in the --if compiled section is only executed in the compiled script. It now also checks whether there is a parameter specified on the command line at run time, using that as the value of n if present, and falling back to the static n value (specified on the command line during compilation, or 10 by default) otherwise. If we run the script normally, in the interpreter, the code in the --else section is executed instead, which just prints a welcome message if no arguments are given on the command line. So we now actually have four different code paths, depending on whether the script is run normally or batch-compiled, with or without arguments. This kind of setup is useful if the script is to be run both interactively and non-interactively in the interpreter while developing it, but once the script is finished it gets compiled and installed as a native executable.

```
$ pure -i -q hello.pure
Try 'main n' where n is a number.
> main 5;
Hello, world!
[1,2,6,24,120]
()
$ quit
```

```
$ pure -o hello -c hello.pure
$ ./hello
Hello, world!
[1,2,6,24,120,720,5040,40320,362880,3628800]
```
You’ll rarely need an elaborate setup like this, most of the time something like our simple first example will do the trick. But, as you’ve seen, Pure can easily do it.

### 1.12.3 Options Affecting Code Size

By default, the batch compiler strips unused functions from the output code, to keep the code size small. You can disable this with the `-u` option, in which case the output code includes all functions defined in the compiled program, the prelude and any other module imported with a `using` clause, even if they don’t seem to be used anywhere. This considerably increases compilation times and makes the compiled executable much larger. For instance, on my 64 bit Linux systems with ELF binaries the executable of our hello.pure example is about twice as large:

```
$ pure -o hello -c -x hello.pure 7 && ls -l hello
-rwxr-xr-x 1 ag ag 337304 Apr 10 19:24 hello
```

(And even the stripped executable is fairly large when compared to compiled C code, as it still contains the symbol table of the entire program, which is needed by the runtime environment.)

Stripped executables should be fine for most purposes, but you have to be careful when using `eval` in your compiled program. The compiler only does a static analysis of which functions might be reached from the initialization code (i.e., top-level expressions and `let` bindings). It does not take into account code run via the `eval` routine. Thus, functions used only in `eval`ed code will be stripped from the executable, as if they were never defined at all. If such a function is then being called using `eval` at runtime, it will evaluate to a plain constructor symbol.

If this is a problem then you can either use the `-u` option to produce an unstripped executable, or you can force specific functions to be included in the stripped executable with the `--required` pragma (cf. Code Generation Options). For instance:

```purescript
#!/ --required foo
foo x = bar (x-1);
 eval "foo 99";
```

There is another code generation option which may have a substantial effect on code size, namely the `--noconst` option. Normally, constant values defined in a `const` definition are precomputed at compile time and then stored in the generated executable; this reduces startup times but may increase the code size considerably if your program contains big constant values such as lists. If you prefer smaller executables then you can use the `--noconst` option to force the value of the constant to be recomputed at run time (which effectively turns the constant into a kind of read-only variable). For instance:
On my 64 bit Linux system this produces a 240 KB executable. Without --noconst the code becomes almost an order of magnitude larger (some 1800 KB). On the other hand, the smaller executable also takes a little longer to run since it must first recompute the value of the list constant at startup. So you have to consider the tradeoffs in a given situation. Usually big executables aren’t much of a problem on modern operating systems, but if your program contains a lot of big constants then this may become an important consideration. However, if a constant value takes a long time to compute then you’ll be better off with the default behaviour of precomputing the value at compile time.

1.12.4 Other Output Code Formats

Note that while the batch compiler generates native executables by default, it can just as well create object files which can be linked into other C/C++ programs and libraries:

```bash
$ pure -o hello.o -c -x hello.pure 7
```

The .o extension tells the compiler that you want an object file. When linking the object module, you also need to supply an initialization routine which calls the __pure_main__ function in hello.o to initialize the compiled module. This routine is declared in C/C++ code as follows:

```c
extern "C" void __pure_main__(int argc, char ** argv);
```

As indicated, __pure_main__ is to be invoked with two parameters, the argument count and NULL-terminated argument vector which become the argc and the argv of the Pure program, respectively. (You can also just pass 0 for both arguments if you don’t need to supply command line parameters.) The purpose of __pure_main__ is to initialize a shell instance of the Pure interpreter which provides the minimal runtime support necessary to execute the Pure program, and to invoke all “initialization code” (variable definitions and toplevel expressions) of the program itself.

A minimal C main function which does the job of initializing the Pure module looks as follows:

```c
extern void __pure_main__(int argc, char** argv);

int main(int argc, char** argv)
{
    __pure_main__(argc, argv);
    return 0;
}
```

If you link the main routine with the Pure module, don’t forget to also pull in the Pure
runtime library. Assuming that the above C code is in pure_main.c:

```bash
$ gcc -c pure_main.c -o pure_main.o
$ g++ -o hello hello.o pure_main.o -lpure
$ ./hello
Hello, world!
```

The C++ compiler is used as the linker here so that the standard C++ library gets linked in, too. This is necessary because Pure’s runtime library is actually written in C++.

In fact, this is pretty much what `pure -c` actually does for you when creating an executable.

If your script loads dynamic libraries (using "lib:"); then you’ll also have to link with those; all external references have to be resolved at compile time. This is taken care of automatically when creating executables. Otherwise it is a good idea to run `pure -c` with the `-v0100` verbosity option so that it prints the libraries to be linked (in addition to the commands which are invoked in the compilation process):

```bash
$ pure -v0100 -c hello.pure -o hello.o
opt -f -std-compile-opts hello.o.bc | llc -f -o hello.o.s
gcc -c hello.o.s -o hello.o
Link with: g++ hello.o -lpure
```

Well, we already knew that, so let’s consider a slightly more interesting example from Pure’s ODBC module:

```bash
$ pure -v0100 -c pure-odbc/examples/menagerie.pure -o menagerie.o
opt -f -std-compile-opts menagerie.o.bc | llc -f -o menagerie.o.s
gcc -c menagerie.o.s -o menagerie.o
Link with: g++ menagerie.o /usr/local/lib/pure/odbc.so -lpure
$ g++ -shared -o menagerie.so menagerie.o /usr/local/lib/pure/odbc.so -lpure
```

Note that the listed link options are necessary but might not be sufficient; `pure -c` just makes a best guess based on the Pure source. On most systems this will be good enough, but if it isn’t, you can just add options to the linker command as needed to pull in additional required libraries.

As this last example shows, you can also create shared libraries from Pure modules. However, on some systems you may have to pass the `-fPIC` option when batch-compiling the module, so that position-independent code is generated:

```bash
$ pure -c -fPIC pure-odbc/examples/menagerie.pure -o menagerie.o
```

**Note:** On most systems it shouldn’t be necessary to specify `-fPIC` explicitly any more, since the compiler will add that option automatically on platforms known to require it. Also note that even when building a shared module, you’ll have to supply an initialization routine which calls `__pure_main__` somewhere.

Since Pure doesn’t support separate compilation in the present implementation, if you create different shared modules like this, each will contain their own copy of all the required Pure
functions from the prelude and other imported Pure modules. This becomes a problem when trying to link several separate batch-compiled modules into the same executable or library, because you’ll get many name clashes for routines present in different modules (including the \texttt{\_\_pure\_main\_\_} entry point). To prevent this, the batch compiler can be invoked with the \texttt{--main} option to explicitly set a name for the main entry point. For instance:

\$ pure -c hello.pure -o hello.o --main \_\_hello\_main\_\_

This has two effects. First, the main entry point will be called whatever you specified with \texttt{--main}, so you have to call this function instead of \texttt{\_\_pure\_main\_\_} to initialize the module. Second, if \texttt{--main} is specified, then all Pure functions in the module will be changed to internal linkage (like static functions in C) to prevent any possible name clashes between different modules. (Alas, this also makes it impossible to employ \texttt{pure\_funcall} to call Pure functions directly from C, as described in the following section, so you’ll have to use other runtime routines such as \texttt{pure\_eval} or \texttt{pure\_appl} to achieve this in an indirect way.)

The batch compiler also lets you pass some special options to the llc program when creating a native assembler or object file. The present implementation understands options of the form \texttt{-mopt=val} which can be used to select the desired target architecture and cpu type. For instance:

\$ pure -march=x86-64 -mcpu=generic -c hello.pure -o hello

This is useful, in particular, in cross compilation and if you need to select a specific processor variant. If you do not specify these options, llc will pick a suitable default based on the characteristics of the host system on which the code is compiled. Please check the documentation of the llc program for further information.

For more elaborate uses not covered by the options discussed above, \texttt{pure -c} can also generate just plain LLVM assembler code:

\texttt{pure -c hello.pure -o hello.ll}

Note the .ll extension; this tells the compiler that you want an LLVM assembler file. An LLVM bitcode file can be created just as easily:

\texttt{pure -c hello.pure -o hello.bc}

In these cases you’ll have to have to handle the rest of the compilation yourself. This gives you the opportunity, e.g., to play with more advanced optimization and code generation options provided by the LLVM toolchain. Please refer to the LLVM documentation (in particular, the description of the opt and llc programs) for details.

1.12.5 Calling Pure Functions From C

Another point worth mentioning here is that you can’t just call Pure functions in a batch-compiled module directly. That’s because in order to call a Pure function, at least in the current implementation, you have to set up a Pure stack frame for the function. However, there’s a convenience function called \texttt{pure\_funcall} in the runtime API to handle this. This function takes a pointer to the Pure function, the argument count and the arguments themselves (as \texttt{pure\_expr*} objects) as parameters. For instance, here is a \texttt{pure\_main.c} module.
which can be linked against the hello.pure program from above, which calls the \texttt{fact} function from the Pure program:

\begin{verbatim}
#include <stdio.h>
#include <pure/runtime.h>

extern void __pure_main__(int argc, char** argv);
extern pure_expr *fact(pure_expr *x);

int main()
{
    int n = 10, m;
    __pure_main__(0, NULL);
    if (pure_is_int(pure_funcall(fact, 1, pure_int(n)), &m))
        printf("fact %d = %d
", n, m);
    return 0;
}
\end{verbatim}

And here’s how you can compile, link and run this program:

\begin{verbatim}
$ pure -o hello.o -c -x hello.pure 7
$ gcc -o pure_main.o -c pure_main.c
$ g++ -o myhello hello.o pure_main.o -lpure
$ ./myhello
Hello, world!
[1,2,6,24,120,720,5040]
fact 10 = 3628800
\end{verbatim}

Note that the first two lines are output from the Pure program; the last line is what gets printed by the \texttt{main} routine in pure\_main.c.

### 1.13 Caveats and Notes

This section is a grab bag of casual remarks, useful tips and tricks, and information on common pitfalls, quirks and limitations of the current implementation and how to deal with them.

#### 1.13.1 Etymology

People keep asking me what’s so “pure” about Pure. The long and apologetic answer is that Pure tries to stay as close as possible to the spirit of term rewriting without sacrificing practicality. Pure’s term rewriting core is in fact purely functional. It’s thus possible and in fact quite easy to write purely functional programs in Pure, and you’re encouraged to do so whenever this is reasonable. On the other hand, Pure doesn’t get in your way if you want to call external operations with side effects; after all, it does allow you to call any C function at any point in a Pure program.

The short answer is that I simply liked the name, and there wasn’t any programming language named “Pure” yet (quite a feat nowadays), so there’s one now. If you insist on a (recursive) backronym, just take “Pure” to stand for the “Pure universal rewriting engine”.
1.13.2 Backward Compatibility

Pure is based on the author’s earlier Q language, but it offers many new and powerful features and programs run much faster than their Q equivalents. The language also went through a thorough facelift in order to modernize the syntax and make it more similar to other modern-style functional languages, in particular Miranda and Haskell. Thus porting Q scripts to Pure often involves a substantial amount of manual work, but it can (and has) been done.

Since its modest beginnings in April 2008, Pure has gone through a lot of major and minor revisions which raise various backward compatibility issues. We document these in the following, in order to facilitate the porting of older Pure scripts. (Note that this isn’t intended to be a full history of Pure development, so you may want to consult the NEWS and ChangeLog files included in the distribution for more details.)

Pure 0.7 introduced built-in matrix structures, which called for some minor changes in the syntax of comprehensions and arithmetic sequences. Specifically, the template expression and generator/filter clauses of a comprehension are now separated with | instead of ;. Moreover, arithmetic sequences with arbitrary stepsize are now written x:y..z instead of x,y..z, and the ’..’ operator now has a higher precedence than the ’,’ operator. This makes writing matrix slices like x!!(i..j,k..l) much more convenient.

In Pure 0.13 the naming of the logical and bitwise operations was changed, so that these are now called ~, &&, || and not/and/or, respectively. (Previously, ~ was used for bitwise, not for logical negation, which was rather inconsistent, albeit compatible with the naming of the not operation in Haskell and ML.) Also, to stay in line with this naming scheme, inequality was renamed to ~=(previously !=).

Pure 0.14 introduced the namespaces feature. Consequently, the scope of private symbols is now confined to a namespace rather than a source module; scripts making use of private symbols need to be adapted accordingly. Also note that syntax like foo::int may now also denote a qualified symbol rather than a tagged variable, if foo has been declared as a namespace. You can work around such ambiguities by renaming the variable, or by placing spaces around the ’::’ delimiter (these aren’t permitted in a qualified symbol, so the construct foo :: int is always interpreted as a tagged variable, no matter whether foo is also a valid namespace).

Pure 0.26 extended the namespaces feature to add support for hierarchical namespaces. This means that name lookup works in a slightly different fashion now (see Hierarchical Namespaces for details), but old code which doesn’t use the new feature should continue to work unchanged.

Pure 0.26 also changed the nullary keyword to nonfix, which is more consistent with the other kinds of fixity declarations. Moreover, the parser was enhanced so that it can cope with a theoretically unbounded number of precedence levels, and the system of standard operators in the prelude was modified so that it becomes possible to sneak in new operator symbols with ease; details can be found in the Symbol Declarations section.

Pure 0.41 added support for optimization of indirect tail calls, so that any previous restrictions on the use of tail recursion in indirect function calls and mutually recursive globals
have been removed. Moreover, the logical operators && and || are now tail-recursive in their second operand and can also be extended with user-defined equations, just like the other builtins. Note that this implies that the values returned by && and || aren’t normalized to the values 0 and 1 any more (this isn’t possible with tail call semantics). If you need this then you’ll have to make sure that either the operands are already normalized, or you’ll have to normalize the result yourself.

Also, as of Pure 0.41 the batch compiler produces stripped executables by default. To create unstripped executables you now have to use the -u option, see Options Affecting Code Size for details. The -s option to produce stripped executables is still provided for backward compatibility, but it won’t have any effect unless you use it to override a previous -u option.

Pure 0.43 changed the rules for looking up symbols in user-defined namespaces. Unqualified symbols are now created in the current (rather than the global) namespace by default, see Symbol Lookup and Creation for details. The -w option can be used to get warnings about unqualified symbols which are resolved to a different namespace than previously. It also provides a means to check your scripts for implicit declarations which might indicate missing or mistyped function symbols.

Pure 0.45 added support for checking arbitrary pointer types in the C interface, so that you don’t have to worry about passing the wrong kinds of pointers to system and library routines any more. Moreover, the interpretation of numeric pointer arguments (int* etc.) was changed to bring them in line with the other new numeric matrix conversions (int** etc.). In particular, the matrix data can now be modified in-place and type checking is more strict (int* requires an int matrix, etc.). Also, there’s now support for argv-style vector arguments (char** and void**). Please see the C Types section for details.

Pure 0.47 added a bunch of new features which have been on the wishlist for the forthcoming 1.0 release:

• You can now define your own interactive commands by placing suitable function definitions in the special __cmd__ namespace; see User-Defined Commands for details.

• The syntax used to denote inline code sections was changed from %{...%} to %<...%>. This resolves an ambiguity in the syntax (note that %{ is legal Pure syntax; it could denote a % operator followed by a matrix value), and also makes it easier to properly support this construct in Emacs Pure mode.

• It is now possible to declare variadic externs, so that functions like printf can be called without much ado; see Variadic C Functions.

• Support for simple kinds of matrix patterns like {x,y}, {x::int,y}, {x,y;z,t}, {{x,y},z} was added.

• The meaning of quoted specials such as lambdas and local definitions was changed. Previously these would be evaluated even in the middle of a quoted expression. Now they will produce a special meta representation in terms of built-in macros, in order to support the advanced metaprogramming capabilities discussed in Built-in Macros and Special Expressions and Reflection.

• Last but not least, Pure 0.47 sports a new, more flexible type tag feature which defines type tags as unary predicates implemented using normal rewriting rules; cf. section...
Type Rules for details. To these ends, a new keyword type was added (if you used this as an ordinary identifier, you will have to rename these). Note that the old-style type tags, which were just a syntactic shortcut for “as” patterns involving unary constructor symbols, aren’t supported any more, so you’ll have to fix up your old scripts accordingly. To assist with this, the Pure interpreter can be run with the \texttt{-w} option in order to identify occurrences of undefined (presumably old-style) type tags. You should either change these to the corresponding “as” pattern (i.e., \texttt{x::foo} to \texttt{x@(foo _)}), or just add a proper type definition for the tag (like \texttt{type foo (foo _);}).

Pure 0.48 moved pointer arithmetic and the regex functions into separate pointers and regex modules, so you now have to import these modules if you need this functionality. It also introduced the \texttt{--defined} pragma which lets you have “defined” functions in Pure which throw an exception if they can’t be applied, e.g., because they are invoked with the wrong arguments.

Pure 0.49 introduced the conditional compilation pragmas, so that simple version and system dependencies can now be handled in a more convenient way.

Pure 0.50 introduced the declaration of interface types, which make it possible to create the definition of a type from a description of its operations. To these ends, a new keyword interface was added to the language.

Pure 0.55 changed the default compilers for inline C, C++ and Fortran code to clang, clang++ and gfortran (with the dragonegg plugin), respectively. This was done in order to support LLVM 3.x which does not have llvm-gcc (the previous default) any more. If you’re still running an older LLVM version and would like to keep using llvm-gcc, you will have to set some environment variables; please see the installation instructions for details.

Pure 0.56 fixed the meaning of patterns in comprehensions so that unmatched elements are now filtered out automatically, like in Haskell. The previous behaviour of raising an exception in such cases offered no real benefits and was in fact very inconvenient in most situations. Pure 0.56 also enables stack checks by default (see Stack Size and Tail Recursion for details), and interactive commands can optionally be escaped by prefixing them with a special character (see Command Syntax). The \texttt{true} and \texttt{false} constants are now declared as nonfix symbols in the prelude so that they can be used in patterns.

Pure 0.58 made the \texttt{-x} option optional, so that a script can now be invoked with arguments simply as \texttt{pure script arg1 arg2 ...}, which matches the default behaviour of most other command language interpreters. This also has the advantage that shebangs like \texttt{#!/usr/bin/env pure} can now be used without any caveats. If you do want to execute multiple script files in batch mode then you now have to explicitly indicate this with the new \texttt{-b} option; please see Invoking Pure for details. Pure 0.58 also adds two new code generation options \texttt{--symbolic} and \texttt{--nosymbolic} to set the default evaluation mode of global functions; these are discussed in Defined Functions below.

Pure 0.66 fixed the treatment of unary/binary minus in custom namespaces. The compiler now handles this by manufacturing a corresponding unary minus operator and an accompanying neg function symbol in the same namespace, so that the overloaded - operator works in exactly the same manner as the default one.

Pure 0.68 changed the batch compiler so that plain toplevel expressions are not evaluated
during batch compilation any more. Thus the compiling variable is obsolete now. It is still supported for backward compatibility, but the compiler will flag it as “deprecated” when run with the -w option. Please check Batch Compilation for details.

### 1.13.3 Error Recovery

The parser uses a fairly simplistic panic mode error recovery which tries to catch syntax errors at the toplevel only. This seems to work reasonably well, but might catch some errors much too late. Unfortunately, Pure’s terseness makes it rather difficult to design a better scheme. As a remedy, the parser accepts an empty definition (just ; by itself) at the toplevel only. Thus, in interactive usage, if the parser seems to eat away your input without doing anything, entering an extra semicolon or two should break the spell, putting you back at the toplevel where you can start typing the definition again.

### 1.13.4 Splicing Tuples and Matrices

The “splicing” of tuples and matrices is probably one of Pure’s most controversial features. By this we mean that tuples and matrices get flattened out when they are combined. For instance:

```
> (1,2,3),4,(5,6);
1,2,3,4,5,6
> {{1,2,3},4,{5,6}};
{1,2,3,4,5,6}
> {{a,b;c,d},{x;y}};
{a,b;x;c,d,y}
```

This kind of behaviour is also known from Perl and MATLAB/Octave. Users familiar with these languages often find it convenient, but it certainly gets in the way if you want to nest these structures. Fortunately, there are some remedies for the most common cases where you’d want to do this. Specifically, for the case of vectors the prelude defines the non-splicing vector brackets which make it easy to construct nested vectors; these are often used to represent multi-dimensional indexable collections in Pure. For instance:

```
> {{|{1,2,3},4,{5,6}|}};
{{1,2,3},4,\{5,6\}}
> {{|{a,b;c,d},\{x;y\}|}};
{{a,b;c,d},\{x;y\}}
> ans!0!(1,1);
d
```

Nothing like this is available for tuples, though, so you’ll have to use lists instead if you need nestability. Note that the deeper reason behind the non-nestability of tuples is the right-recursive nature of tuples combined with the fact that there aren’t any real 1-tuples in Pure ((x) is just x). This implies that you can’t have a nested tuple in the last component of a tuple, no matter how hard you try to prevent the splicing, e.g., by quoting. x, (y, z) is always just the triple x, y, z.

One might consider this a defect in Pure’s tuple data structure. But Pure already has a nestable kind of tuples (lists), so it would be rather pointless to have yet another isomorphic
data structure with just slightly different syntax. Instead Pure gives you the choice between two kinds of list-like data structures, one which nests, and one which doesn’t but has other interesting properties.

### 1.13.5 With and when

Another common source of confusion is that Pure provides two different constructs to bind local function and variable symbols, respectively. This distinction is necessary because Pure does not segregate defined functions and constructors, and thus there is no magic to figure out whether an equation like `foo x = y` by itself is meant as a definition of a function `foo` with formal parameter `x` and return value `y`, or a pattern binding defining the local variable `x` by matching the pattern `foo x` against the value of `y`. The `with` construct does the former, `when` the latter.

Also note that the function definitions in a `with` clause are all done simultaneously (and can thus be mutually recursive), while the individual variable definitions and expressions in a `when` clause are executed in order. This works in exactly the same fashion as `letrec` and `let` in Scheme. (As a mnemonic, consider that `when` conveys a sense of time, so its parts are “executed in sequence”.)

The sequential execution aspect of `when` is rather important in Pure, because it enables you to do a series of “actions” (variable bindings and expression evaluations) in sequence by simply enclosing it in a `when` clause. This provides the Pure programmer with a useful and familiar bit of imperative “look and feel” (even though the `when` clause itself works in a purely functional way). For instance, suppose that we’d like to define a function which opens a file, checks that the file was opened successfully and throws an exception otherwise, outputs a message to indicate which file was opened, and finally returns the contents of the file as a string. The easiest way to do this in Pure is as follows:

```pure
using system;

read_file name::string = s when
  fp = fopen name "r";
  interp fp [] throw (sprintf "%s: %s" (name, strerror errno));
  printf "opened file %s
" name;
  s = fget fp;
end;
```

Another bit of syntax that may take getting used to is that `with` and `when` clauses are tack on to the end of the expression they belong to. This mimics mathematical language and supposedly makes it easier to read and understand a definition, because you’re told right up front what is to be computed, before going into the details of how the computation is performed. Unfortunately, this style differs considerably from other block-structured programming languages, which often place local definitions in front of the code they apply to. Pure doesn’t offer any special syntax for this, but note that you can always write a `when` or `with` clause in the following style which places the “body” at the bottom:

```pure
result when
  y = foo (x+1);
  z = bar y;
```
result = baz z;
end;

This can be read and written more or less like a let expression in Scheme or ML, except that
the name of the result is given explicitly at the beginning. However, this style doesn’t really
save you either if you need several sections with both local functions and variables. In this
case you’ll just have to bite the bullet and arrange the with and when clauses the way that
Pure wants them. That is, first come the local variables used in the right-hand side, then
the local functions needed to compute those variables, then maybe another section with
local variables needed by those functions, etc. When looking at such a complicated series
of definitions, it sometimes helps to read the with and when blocks “in reverse”, i.e., from
bottom to top, which is the order in which they will actually be executed.

1.13.6 Non-Linear Patterns

As explained in section Patterns, Pure allows multiple occurrences of the same variable in a
pattern (so-called non-linearities):

foo x x = x;

This rule will only be matched if both occurrences of x are bound to the same value. More
precisely, the two instances of x will be checked for syntactic equality during pattern match-
ing, using the same primitive provided by the prelude. This may need time proportional to
the sizes of both argument terms, and thus become quite costly for big terms. In fact, same
might not even terminate at all if the compared terms are both infinite lazy data structures,
such as in foo (1..inf) (1..inf). So you have to be careful to avoid such uses.

When using non-linearities in conjunction with “as” patterns, you also have to make sure
that the “as” variable does not occur inside the corresponding subpattern. Thus a definition
like the following is illegal:

> foo xs@(x:xs) = x;
<stdin>, line 1: error in pattern (recursive variable ‘xs’)

The explanation is that such a pattern couldn’t possibly be matched by a finite list anyway.
Indeed, the only match for xs@(x:xs) would be an infinite list of x’s, and there’s no way that
this condition could be verified in a finite amount of time. Therefore the interpreter reports
a “recursive variable” error in such situations.

1.13.7 “As” Patterns

In the current implementation, “as” patterns cannot be placed on the “spine” of a function
definition. Thus rules like the following, which have the pattern somewhere in the head of
the left-hand side, will all provoke an error message from the compiler:

a@foo x y = a,x,y;
a@(foo x) y = a,x,y;
a@(foo x y) = a,x,y;
This is because the spine of a function application is not available when the function is called at runtime. "As" patterns in pattern bindings (let, const, case, when) are not affected by this restriction since the entire value to be matched is available at runtime. For instance:

```plaintext
> case bar 99 of y@(bar x) = y, x+1; end;
bar 99,100
```

### 1.13.8 "Head = Function" Pitfalls

The "head = function" rule stipulates that the head symbol f of an application f x1 ... xn occurring on (or inside) the left-hand side of an equation, variable binding, or pattern-matching lambda expression, is always interpreted as a literal function symbol (not a variable). This implies that you cannot match the "function" component of an application against a variable, at least not directly. An anonymous "as" pattern like f@_. does the trick, however, since the anonymous variable is always recognized, even if it occurs as the head symbol of a function application. Here's a little example which demonstrates how you can convert a function application to a list containing the function and all arguments:

```plaintext
> foo x = a [] x with a xs (x@_ y) = a (y:xs) x; a xs x = x:xs end;
> foo (a b c d);
[a,b,c,d]
```

This may seem a little awkward, but as a matter of fact the "head = function" rule is quite convenient, since it covers the common cases without forcing the programmer to declare variable or constructor symbols (other than nonfix symbols). On the other hand, generic rules operating on arbitrary function applications are not all that common, so having to "escape" a variable using the anonymous "as" pattern trick is a small price to pay for that convenience.

Sometimes you may also run into the complementary problem, i.e., to match a function argument against a given function. Consider this code fragment:

```plaintext
foo x = x+1;
foop f = case f of foo = 1; _ = 0 end;
```

You might expect foop to return true for foo, and false on all other values, but in reality foop will always return true! In fact, the Pure compiler will warn you about the second rule of the case expression not being used at all:

```plaintext
> foop 99;
warning: rule never reduced: _ = 0;
1
```

This is again due to the "head = function" rule; foo is neither the head symbol of a function application nor a nonfix symbol here, so it is considered a variable, even though it is defined as a global function elsewhere. (As a matter of fact, this is rather useful, since otherwise a rule like f g = g+1 would suddenly change meaning if you happen to add a definition like g x = x-1 somewhere else in your program, which certainly isn’t desirable.)

A possible workaround is to "escape" the function symbol using an empty namespace qualifier:
foop f = case f of ::foo = 1; _ = 0 end;

This trick works in case expressions and function definitions, but fails in circumstances in
which qualified variable symbols are permitted (i.e., in variable and constant definitions).
A better solution is to employ the syntactic equality operator === defined in the prelude
to match the target value against the function symbol. This allows you to define the foop
predicate as follows:

> foop f = f===foo;
> foop foo, foop 99;
1,0

Another way to deal with the situation would be to just declare foo as a nonfix symbol.
However, this makes the foo symbol “precious”, i.e., after such a declaration it cannot be
used as a local variable anymore. It’s usually a good idea to avoid that kind of thing, at least
for generic symbols, so the above solution is preferred in this case.

### 1.13.9 Defined Functions

As explained in Definitions and Expression Evaluation, Pure doesn’t really distinguish “con-
structors” from “defined functions” and thus allows any function symbol to become part of
a normal form expression yielded by an evaluation. This behaviour follows the usual se-
mantics of (typeless) term rewriting and is essential if you also want to evaluate expressions
symbolically.

However, this becomes a nuisance if you really expect the given function to reduce to some-
ting else, and just accidentally supplied the wrong arguments to the function. Especially
annoying in this respect are functions involving side effects:

> using system;
> puts 99;
puts 99

Here we accidentally specified a number (rather than a string) as the argument of the puts
function. This kind of error can easily be spotted if the function is invoked interactively, but
it may well go unnoticed if the call is buried deeply in a big program which runs unattended
(in batch mode).

As a remedy, Pure 0.48 introduces the --defined pragma (cf. Code Generation Options)
which allows you to explicitly declare a function symbol as a “defined” function, so that
it will raise a proper exception when the defining equations (or, as it were, the external
definition) of the function are not applicable to the subject expression:

> #! --defined puts
> puts 99;
<stdin>, line 4: unhandled exception ‘failed_match’ while evaluating ‘puts 99’

This is the same kind of failed_match exception that you’ll get, e.g., if the subject term fails
to match all patterns in a case construct, cf. Exception Handling.
Note that the `--defined` pragma only has an effect on global functions; local functions in a `with` expression will always be evaluated in Pure’s default symbolic mode. Thus, if you need the above behaviour with a local function then you’ll either have to add the exception handling yourself or turn the local function into a global one.

Also note that an exception will only be generated if the symbol actually has any defining equations, so a “pure constructor” (i.e., a symbol without defining equations) will still return a normal form even if it is also declared `--defined`:

```plaintext
> #! --defined foo
> foo bar;
foo bar
```

Nevertheless, the `--defined` pragma will be recorded and take effect as soon as you add an equation for the function:

```plaintext
> foo x::int = x+1;
> foo bar;
<stdin>, line 4: unhandled exception 'failed_match' while evaluating 'foo bar'
```

There’s also a `--nodefined` pragma which reverts the function to the default behaviour of returning normal forms:

```plaintext
> #! --nodefined foo
> foo bar;
foo bar
```

As indicated, the `--defined` and `--nodefined` pragmas can be invoked freely at any time, and the interpreter takes care that the affected function is recompiled automatically as needed.

Pure 0.58 and later also provide a `--nosymbolic` compilation option which lets you switch the interpreter to the non-symbolic mode of operation, so that every global function with equations becomes a defined function. This option is most commonly used as a pragma to delineate code sections with defined functions, so that you don’t have to write out the `--defined` pragmas for each function. The `--symbolic` pragma is then used to switch back to the default symbolic mode. For instance:

```plaintext
> run
> #! --nosymbolic
> extern int puts(char*);
> foo x::int = x+1;
> puts 99;
<stdin>, line 4: unhandled exception 'failed_match' while evaluating 'puts 99'
> foo bar;
<stdin>, line 5: unhandled exception 'failed_match' while evaluating 'foo bar'
> #! --symbolic
> bar x::int = x-1;
> bar foo;
bar foo
```

Note that these pragmas only adjust the default behaviour of functions. It is still possible to change the status of individual functions with the `--defined` and `--nodefined` pragmas:
You can even invoke the interpreter with the --nosymbolic command line option so that the non-symbolic mode becomes the global default. However, this affects all functions in a program, including the library functions used by your program. It isn’t really advisable to do this, because at the time of this writing many library modules still assume Pure’s default mode of symbolic evaluation, and so a global switch to --nosymbolic may well break some of these functions.

At this time, the --defined and --nosymbolic pragmas are still considered experimental. They interfere with Pure’s symbolic evaluation capabilities, so they aren’t currently used in the standard library and we recommend that programmers shouldn’t use them in a careless fashion either. However, while most error conditions stemming from unexpected normal forms can also be caught with diligent unit testing, these pragmas can save you time and trouble, especially when testing programs which are to be executed mostly in batch mode. Future versions of the interpreter might also make good use of these pragmas for static checks and optimization purposes.

### 1.13.10 Stack Size and Tail Recursion

Pure programs may need a considerable amount of stack space to handle recursive function and macro calls, and the interpreter itself also takes its toll. So you should configure your system accordingly (8 MB of stack space is recommended for 32 bit systems, systems with 64 bit pointers probably need more). The interpreter automatically performs advisory stack checks on function entry and raises a Pure exception if the current stack size exceeds a given limit. A reasonable default for the stack limit is defined by the implementation, please check the description of the PURE_STACK environment variable for details.

You can also change this limit if needed, by setting the PURE_STACK environment variable accordingly. The value of PURE_STACK should be the maximum stack size in kilobytes. Please note that this is only an advisory limit which does not change the program’s physical stack size, so you can set this to any value that seems appropriate. (You can also set PURE_STACK to zero to completely disable the checks, but this isn’t recommended.) Your operating system should supply you with a command such as ulimit(1) to set the real process stack size. (The PURE_STACK limit should be a little less than that, to account for temporary stack usage by the interpreter itself.)

Like Scheme, Pure does proper tail calls (if LLVM provides that feature on the platform at hand), so tail-recursive definitions should work fine in limited stack space. For instance, the following little program will loop forever if your platform supports the required optimizations:

```pure
loop with loop = loop end;
```
This also works if your definition involves function parameters, guards and multiple equations, of course. Moreover, conditional expressions (if-then-else) are tail-recursive in both branches, and the logical operators && and ||, as well as the sequence operator $$, are tail-recursive in their second operand.

In addition, the Pure compiler also does a specialized form of tail recursion optimization for type definition rules. Due to the special way in which type tags are processed, however, the amount of optimization performed in this case is somewhat limited; see Recursive Types below.

Finally, note that tail call optimization is always disabled if the debugger is enabled (-g). This makes it much easier to debug programs, but means that you may run into stack overflows when debugging a program that does deep tail recursion.

1.13.11 Handling of Asynchronous Signals

As described in section Exception Handling, signals delivered to the process can be caught and handled with Pure’s exception handling facilities. This has its limitations, however. Since Pure code cannot be executed directly from a C signal handler, checks for pending signals are only done on function entry. This means that in certain situations (such as the execution of an external C routine), delivery of a signal may be delayed by an arbitrary amount of time. Moreover, if more than one signal arrives between two successive signal checks, only the last one will be reported in the current implementation.

When delivering a signal which has been remapped to a Pure exception, the corresponding exception handler (if any) will be invoked as usual. Further signals are blocked while the exception handler is being executed.

A fairly typical case is that you have to handle signals in a tail-recursive function. This can be done with code like the following:

```pure
using system;

// Remap some common POSIX signals.
do (trap SIG_TRAP) [SIGHUP, SIGINT, SIGTERM];

loop = catch handler process $$ loop
  with handler (signal k) = printf "Hey, I got signal %d.\n" k end;
process = sleep 1; // do something
```

Running the above loop function enters an endless loop reporting all signals delivered to the process. Note that to make this work, the tail-recursive invocation of loop must immediately follow the signal-handling code, so that signals don’t escape the exception handler.

Of course, in a real application you’d probably want the loop function to carry around some data to be processed by the process routine, which then returns an updated value for the next iteration. This can be implemented as follows:

```pure
loop x = loop (catch handler (process x))
  with handler (signal k) = printf "Hey, I got signal %d.\n" k $$ 0 end;
process x = printf "counting: %d\n" x $$ sleep 1 $$ x+1;
```

1.13.11 Handling of Asynchronous Signals 231
1.13.12 Recursive Types

Using the facilities described in Type Rules, type tags can easily be defined in a recursive fashion. In simple cases, the compiler can optimize such definitions so that they are executed in constant stack space, just like ordinary tail-recursive functions. The main difference here is that the recursion already takes place during matching, i.e., on the left-hand side of a rule, since this is where type predicates are normally invoked. This also limits the amount of tail recursion optimization available on type rules, as detailed below.

For instance, the following rlist type from the prelude is defined in such a way that it only matches “proper” lists which have list values in all their tails (and are thus terminated by the empty list).

```haskell
type rlist [] | rlist (x : xs::rlist);
```

Note that this type definition recurses in the last rlist tag of the last rule of the type. If tail calls are supported by the host implementation (cf. Stack Size and Tail Recursion), the compiler makes sure that such definitions are safe to use even if the recursion may go arbitrarily deep. For instance:

```haskell
> typel rlist (1..1000000);
```

The precise rules for tail-recursive type definitions are as follows:

- The last rule of the type must have a trivial right-hand side (either just true or missing) and must be directly recursive in the last type tag on the left-hand side of the rule.
- The rule may not contain any non-linearities. (That’s because these are always checked after the type guards for efficiency.)

While these are rather strict requirements, they work reasonably well for simple recursive types such as the recursive list type above. More general recursion in types will not be optimized by the compiler, however, and may thus be subject to stack overflows. For instance, consider the following binary tree type:

```haskell
nonfix nil;
type tree nil | tree (bin x l::tree r::tree);
```

This is a perfectly legal type definition, and the recursion in the last tree tag of the second rule will indeed be optimized away. However, the second rule also recurses on the first tree tag which will cause trouble if there are long chains of left branches in a tree. For instance:

```haskell
> mktree xs = foldr (\x t->bin x t nil) nil xs;
> mktree [];

nil
> mktree [1,2,3];
bin 1 (bin 2 (bin 3 nil nil) nil)
> typel tree (mktree []);
1
> typel tree (mktree [1,2,3]);
1
> typel tree (mktree (1..10000));
```
To avoid deep recursion in such cases it is necessary to implement the type using a general predicate, which handles the recursion by transforming it into a tail-recursive form using a technique like continuation passing.

There’s yet another important issue with recursive type definitions, namely the time it takes to check the definition. In the above example, checking \texttt{rlist} takes $O(n)$ time, where $n$ is the size of the list. This will have dire consequences if you do this check repeatedly while traversing a list, as in the following \texttt{sum} function:

\begin{verbatim}
sum xs::rlist = if null xs then 0 else head xs+sum (tail xs);
\end{verbatim}

As this function repeatedly checks its entire argument, the total time it takes to compute the sum of a list this way becomes $O(n^2)$. To see how slow this function is, just try it on successively larger lists \texttt{1..1000}, \texttt{1..2000}, etc. One way to work around this is to write a “wrapper” function which simply checks the type of its argument in advance and then invokes a “worker” function to do the actual computation:

\begin{verbatim}
sum xs::rlist = sum xs with
  sum xs = if null xs then 0 else head xs+sum (tail xs);
end;
\end{verbatim}

This “wrapper-worker” design is quite common and useful in many situations, but it is a bit cumbersome in this specific case. An easier way is to just do the type checking in a piecemeal fashion, as the list is being traversed. To these ends, the prelude also provides a basic \texttt{list} type which is defined as follows:

\begin{verbatim}
type list [] | list (x:xs);
\end{verbatim}

Note that the recursion is missing here and thus this type can always be checked in $O(1)$ time, performing just a single pattern match, which is efficient. Hence, if we replace \texttt{rlist} with the \texttt{list} type in our original definition then \texttt{sum} will now run in $O(n)$ time, as desired. On the other hand, this approach also has its drawbacks. For instance, consider:

\begin{verbatim}
> sum xs::list = if null xs then 0 else head xs+sum (tail xs);
> sum (1:2:3);
1+(2+sum 3)
\end{verbatim}

In contrast, our wrapper-worker definition of \texttt{sum} from above returns a somewhat prettier normal form instead:

\begin{verbatim}
> clear sum
> sum xs::rlist = sum xs with
>  sum xs = if null xs then 0 else head xs+sum (tail xs);
> end;
> sum {1:2:3};
sum {1:2:3}
\end{verbatim}

Thus the wrapper-worker approach also has its merits, and whether to use one or the other
depends on the situation. Similar techniques and tradeoffs also apply to other recursive
types such as trees.

1.13.13 Interfaces

Pure’s implementation of interface types has some notable differences to interfaces in a stat-
tically typed language like Go. These are mostly due to Pure’s dynamically typed nature.

• Nothing is known about the return type of an interface operation, but this is no real
impediment since Pure types are all about restricting the kind of arguments which can
be passed to a function, not their result types, so return types are irrelevant to Pure’s
interface types anyway.

• Pure interfaces aren’t based on the notion of “methods” and therefore don’t provide
any kind of “method dispatch”. Interface operations are just ordinary Pure functions
which rely on Pure’s usual pattern-matching mechanism to do the dynamic dispatch.

• Membership in interface types is decided by considering the left-hand sides of the
definitions of the interface functions only. Guards are not taken into account, and thus
there’s no real guarantee that a member of an interface type will always be valid input
to an interface function.

• Interface types work best if all interface operations are completely defined on the target
data domain. This may sometimes force you to add default or error rules raising ex-
ceptions, as shown in the Interface Types section, which may interfere with symbolic
evaluation (cf. Exception Handling and Defined Functions). If this is not desirable,
you can also just include the missing members manually. To these ends, Pure allows
an interface type to be augmented with ordinary type rules as described in Type Rules.
For instance, we might also have implemented the stack type discussed in the Interface
Types section as follows:

```
interface stack with
  push s::stack x;
  pop s::stack;
  top s::stack;
end;

type stack [];

  push xs[] x | push xs@(_:_) x = x:xs;
  pop (x:xs) = xs;
  top (x:xs) = x;
```

Pure’s interface types are really a compromise between theoretical soundness and practical-
ity. From the theoretical point of view, we’d like an interface type to be the intersection of
the interface types for the individual interface functions. Unfortunately, the pattern set for such
an intersection type might well be exponential in size. Hence the approach taken in Pure
is to eliminate those candidate patterns which aren’t supported by all interface functions.
This can be done much more efficiently, but will in general only produce a subtype of the
intersection type. (On the other hand, this method also has the advantage that the compiler
can warn about potentially missing rules in some of the interface operations. We’ve seen in the Interface Types section that this can be fairly useful at times.)

Another issue arises with interface operations which allow the interface type in multiple arguments. A typical example are operators:

```plaintext
interface addable with x::addable + y::addable; end;
```

In the present implementation, the pattern set will be the union of the pattern sets for each argument, so the above definition is in fact equivalent to:

```plaintext
interface addable with x::addable + y; x + y::addable; end;
```

This makes sense in many situations, but of course this depends on the particular operation. In some cases, you might have to decide on which argument you want to place the interface type tag, or even have different types for each possible argument position.

### 1.13.14 Numeric Calculations

If possible, you should decorate numeric variables on the left-hand sides of function definitions with the appropriate type tags, like `int` or `double`. This often helps the compiler to generate better code and makes your programs run faster. The `|` syntax makes it easy to add the necessary specializations of existing rules to your program. E.g., taking the polymorphic implementation of the factorial as an example, you only have to add a left-hand side with the appropriate type tag to make that definition go as fast as possible for the special case of machine integers:

```plaintext
fact n::int | fact n = n*fact(n-1) if n>0;
= 1 otherwise;
```

(This obviously becomes unwieldy if you have to deal with several numeric arguments of different types, however, so in this case it is usually better to just use a polymorphic rule.)

Also note that `int` (the machine integers), `bigint` (the GMP “big” integers) and `double` (floating point numbers) are all different kinds of objects. While they can be used in mixed operations (such as multiplying an int with a bigint which produces a bigint, or a bigint with a double which produces a double), the int tag will only ever match a machine int, not a bigint or a double. Likewise, `bigint` only matches bigints (never int or double values), and `double` only doubles. Thus, if you want to define a function operating on different kinds of numbers, you’ll also have to provide equations for all the types that you need (or a polymorphic rule which catches them all). This also applies to equations matching against constant values of these types. In particular, a small integer constant like 0 only matches machine integers, not bigints; for the latter you’ll have to use the “big L” notation 0L. Similarly, the constant 0.0 only matches doubles, but not ints or bigints.

### 1.13.15 Constant Definitions

Constants differ from variables in that they cannot be redefined (that’s their main purpose after all) so that their values, once defined, can be substituted into other definitions which
use them. For instance:

```pure
> const c = 2;
> foo x = c*x;
> show foo
foo x = 2*x;
> foo 99;
198
```

While a variable can be rebound to a new value at any time, you will get an error message if you try to do this with a constant:

```pure
> const c = 3;
<stdin>, line 5: symbol 'c' is already defined as a constant
```

Note that in interactive mode you can work around this by purging the old definition with the `clear` command. However, this won’t affect any earlier uses of the symbol:

```pure
> clear c
> const c = 3;
> bar x = c*x;
> show foo bar
bar x = 3*x;
foo x = 2*x;
```

(You’ll also have to purge any existing definition of a variable if you want to redefine it as a constant, or vice versa, since Pure won’t let you redefine an existing constant or variable as a different kind of symbol. The same also holds if a symbol is currently defined as a function or a macro.)

Constants can also be used in patterns (i.e., on the left-hand side of a rule in a definition or a `case` expression), but only if they’re also declared as `nonfix`. The prelude already does this for the truth values `true` and `false` (which are in fact just 1 and 0), so that you can write, e.g.:

```pure
> check false = "no"; check true = "yes";
> show check
check 0 = "no";
check 1 = "yes";
> check (5>0);
"yes"
```

Note that if `true` and `false` weren’t `nonfix`, the above definition of `check` wouldn’t work as intended, because the `true` and `false` symbols on the left-hand side of the two equations would be interpreted as local variables. Also note that `true` and `false` are really an exceptional case; they aren’t likely to be used as variables, so the prelude can make them `nonfix` by default. In most cases the standard library refrains from declaring constant symbols as `nonfix`, so that they don’t accidentally clobber variables in user code. This is the case, in particular, for constants in the `math` module such as `e`, `pi` and `i` which are much more likely to be used as variable symbols.

As the value of a constant is known at compile time, the compiler can apply various opti-
mizations to uses of such values. In particular, the Pure compiler inlines constant scalars (numbers, strings and pointers) by literally substituting their values into the output code. It also precomputes simple constant expressions involving only (machine) integer and double values. (The latter is called **constant folding** and can also be disabled, see the description of the `-fold` and `-nofold` pragmas for details.) Example:

```plaintext
> extern double atan(double);
> const pi = 4*atan 1.0;
> show pi
  const pi = 3.14159265358979;
> foo x = 2*pi+x;
> show foo
  foo x = 6.28318530717959*x;
```

Constant folding also works with conditional expressions. E.g., consider:

```plaintext
const win = index sysinfo "mingw32" >= 0;
check boy = if win then bad boy else good boy;
```

On a Linux system, this gives:

```plaintext
> show check
  check boy = good boy;
```

By these means, you can employ a constant to configure your code for different environments, without any runtime penalties. Note that this only works with conditional expressions, not with guarded equations. However, in the latter case the LLVM backend still eliminates dead code automatically, so the check function from above could also be defined as follows:

```plaintext
check boy = bad boy if win;
    = good boy otherwise;
```

In this case the code for one of the branches of check will be completely eliminated, depending on the outcome of the configuration check. (The interpreter will still print both equations if you type `show check`, but only one of the branches will actually be present in the assembler code of the function; you can verify this with `show -d check`.)

For efficiency, constant aggregates (lists, tuples, matrices and other kinds of non-scalar terms) receive special treatment. Here, the constant is computed once and stored in a read-only variable which then gets looked up at runtime, just like an ordinary global variable. However, there’s an important difference: If a script is batch-compiled (cf. **Batch Compilation**), the constant value is normally computed at compile time only; when running the compiled executable, the constant value is simply reconstructed, which is often much more efficient than recomputing its value. For instance, you might use this to precompute a large table whose computation may be costly or involve functions with side effects:

```plaintext
const table = [foo x | x = 1..1000000];
process table;
```

Note that this only works with `const` values which are completely determined at compile time. If a constant contains run time objects such as (non-null) pointers and (local) functions,
this is impossible, and the batch compiler will instead create code to recompute the value of
the constant at run time. For instance, consider:

```c
const p = malloc 100;
foo p;
```

Here, the value of the pointer `p` of course critically depends on its computation (involving a
side effect which sets aside a corresponding chunk of memory). It would become unusable
without actually executing the initialization, so the compiler generates the appropriate run
time initialization code in this case. For all practical purposes, this turns the constant into a
read-only variable. (There’s also a code generation option to force this behaviour even for
“normal” constants for which it’s not strictly necessary, in order to create smaller executables;
see Options Affecting Code Size for details.)

### 1.13.16 External C Functions

The interpreter always takes your `extern` declarations of C routines at face value. It will
not go and read any C header files to determine whether you actually declared the function
correctly! So you have to be careful to give the proper declarations, otherwise your program
might well give a segfault when calling the function. This problem can to some extent be
alleviated by using the bitcode interface, see Importing LLVM Bitcode and Inline Code in
the C Interface section. However, you always have to be careful when calling variadic C
functions, as the compiler has no way of checking which combinations of extra parameters a
function like `printf` is to be invoked with. (As a remedy, the standard library provides safe
implementations of `printf` and other commonly used variadic functions from the C library,
see the Pure Library Manual for details.)

Another limitation of the C interface is that it does not offer any special support for C structs
and C function parameters. However, an optional addon module is available which interfaces
to the `libffi` library to provide that kind of functionality, please see `pure-ffi` for details.

Last but not least, to make it easier to create Pure interfaces to large C libraries, there’s a
separate pure-gen program available at the Pure website. This program takes a C header
(.h) file and creates a corresponding Pure module with definitions and `extern` declarations
for the constants and functions declared in the header. Please refer to `pure-gen: Pure interface
generator` for details.

### 1.13.17 Calling Special Forms

Special forms are recognized at compile time only. Thus the `catch` function, as well as `quote`
and the operators `&&`, `||`, `$$` and `&`, are only treated as special forms in direct (saturated) calls.
They can still be used if you pass them around as function values or in partial applications,
but in this case they lose all their special call-by-name argument processing.

### 1.13.18 Laziness

Pure does lazy evaluation in the same way as Alice ML, providing an explicit operation
(`&`) to defer evaluation and create a “future” which is called by need. However, note that
like any language with a basically eager evaluation strategy, Pure cannot really support lazy
evaluation in a fully automatic way. That is, coding an operation so that it works with
infinite data structures usually requires additional thought, and sometimes special code will
be needed to recognize futures in the input and handle them accordingly. This can be hard,
but of course in the case of the prelude operations this work has already been done for you,
so as long as you stick to these, you’ll never have to think about these issues. (It should
be noted here that lazy evaluation has its pitfalls even in fully lazy FPLs, such as hidden
memory leaks and other kinds of subtle inefficiencies or non-termination issues resulting
from definitions being too lazy or not lazy enough. You can read about that in any good
textbook on Haskell.)

The prelude goes to great lengths to implement all standard list operations in a way that
properly deals with streams (a.k.a. lazy lists). What this all boils down to is that all list
operations which can reasonably be expected to operate in a lazy way on streams, will do
so. (Exceptions are inherently eager operations such as \#, reverse and foldl.) Only those
portions of an input stream will be traversed which are strictly required to produce the result.
For most purposes, this works just like in fully lazy FPLs such as Haskell. However, there
are some notable differences:

- Since Pure uses dynamic typing, some of the list functions may have to peek ahead
  one element in input streams to check their arguments for validity, meaning that these
  functions will be slightly more eager than their Haskell counterparts.

- Pure’s list functions never produce truly cyclic list structures such as the ones you get,
  e.g., with Haskell’s cycle operation. (This is actually a good thing, because the current
  implementation of the interpreter cannot garbage-collect cyclic expression data; please
  see the corresponding remarks in Expression References for details.) Cyclic streams such
  as cycle [1] or fix (1:) will of course work as expected, but, depending on the
  algorithm, memory usage may increase linearly as they are traversed.

- Pattern matching is always refutable (and therefore eager) in Pure. If you need some-
  thing like Haskell’s irrefutable matches, you’ll have to code them explicitly using fu-
  tures. See the definition of the unzip function in the prelude for an example showing
  how to do this.

There are two other pitfalls with lazy data structures that you should be aware of:

- Laziness and side effects don’t go well together, as most of the time you can’t be sure
  when a given thunk will be executed. So as a general guideline you should avoid
  side effects in thunked data structures. If you can’t avoid them, then at least make
  sure that all accesses to the affected resources are done through a single instance of
  the thunked data structure. E.g., the following definition lets you create a stream of
  random numbers:

  ```
  > using math;
  > let xs = [random | _ = 1..inf];
  ```

  This works as expected if only a single stream created with random exists in your pro-
  gram. However, as the random function in the math module modifies an internal data
  structure to produce a sequence of pseudorandom numbers, using two or more such
  streams in your program will in fact modify the same underlying data structure and
thus produce two disjoint subsequences of the same underlying pseudorandom sequence which might not be distributed uniformly any more.

- You should avoid keeping references to potentially big (or even infinite) thunked data structures when traversing them (unless you specifically need to memoize the entire data structure). In particular, if you assign such a data structure to a local variable, the traversal of the data structure should then be invoked as a tail call. If you fail to do this, it forces the entire memoized part of the data structure to stay in main memory while it is being traversed, leading to rather nasty memory leaks. Please see the all_primes function in Lazy Evaluation and Streams for an example.

1.13.19 Name Capture

As explained in the Macro Hygiene section, Pure macros are lexically scoped and thus “hygienic”. So in principle Pure macros are not susceptible to name capture. However, this principle only applies to “real” block constructs, not their quoted “placeholder” representations described in Built-in Macros and Special Expressions. One (rather obscure) case which deserves special attention is the case of macros involving free variables which are being called inside quoted block constructs. Note that this corresponds to the “mild” first form of name capture described in the Macro Hygiene section. For instance, consider the following example:

```plaintext
> def G x = x+y;
> '(G 10 when y = 99 end);
G 10 __when__ [y-->99]
> eval ans;
10
```

Here the free y variable of the macro G got captured by the quoted when clause when the quoted expression is evaluated. This happens because, using call by value, the call G 10 gets evaluated before the __when__ macro. So the behaviour of the macro evaluator in this case is in fact correct; the only remedy here is to avoid macros involving free variables inside a quoted block construct. The same applies to “quoteargs” macros which quote their arguments automatically, as described in Built-in Macros and Special Expressions. On the other hand, the described behaviour might even be useful at times, to forcibly rebind a free macro variable. The following little helper macro illustrates this trick:

```plaintext
> #! --quoteargs invoke
> def invoke x = x;
> foo = invoke (G 10 when y = 99 end);
> show foo
foo = 10+y when y = 99 end;
> foo;
10
```

Besides the above form of real name capture in quoted specials, there’s also a case of apparent name capture in the expression printer which isn’t actually real name capture, but just looks like it was. The reason for this is that the expression printer currently doesn’t check for different bindings of the same variable identifier when it prints a (compile time) expression. For instance, consider:
> def F x = x+y when y = x+1 end;
> foo y = F y;
> show foo

foo y = y+y when y = y+1 end;

This looks as if y got captured, but in fact it’s not, it’s just the show command which displays the definition in an incorrect way. You can add the -e option to show which prints the de-Bruijn indices of locally bound symbols, then you see that the actual bindings are all right anyway:

> show -e foo

foo y/=0:1/= = y/=1:1=/+y/=0:=/ when y/=0:=/ = y/=0:1=/+1 end;

Note that the number before the colon is the actual deBruijn index, the sequence of bits behind it is the subterm path. Thus the first instance of y in y+y (which has a deBruijn index of 1, indicating “one environment up”) actually refers to the y in the left-hand side foo y, while the second instance refers to the local binding y = y+1 in the when clause.

Alas, this means that if you use dump to write such a definition to a text file and read it back with run later, then the apparent name capture becomes a real one and you’ll get the wrong definition. This is an outright bug in the expression printer which will hopefully be fixed some time. But for the time being you will have to correct such glitches manually.

Albert Gräf <aggraef@gmail.com>, Dept. of Computer Music, Johannes Gutenberg University of Mainz, Germany.

1.15 Acknowledgements

Pure wouldn’t be what it is without its users and other people interested in the language. In particular, I’d like to thank Scott E. Dillard, Rooslan S. Khayrov, Jim Pryor, Eddie Rucker, Libor Spacek, Jiri Spitz, Peter Summerland and Sergei Winitzki for their significant contributions of code, patches and documentation. Thanks are also due to Björn Lindig, Michel Salim, Ryan Schmidt and Zhihao Yuan who maintain the Arch Linux, Fedora, OSX and FreeBSD packages and ports, as well as to Vili Aapro, Jason E. Aten, Alvaro Castro Castilla, John Cowan, Chris Double, Tim Haynes, Wm Leler, John Lunney, Roman Neuhauser and Max Wolf for suggesting improvements and pointing out shortcomings, misfeatures and outright bugs. If it wasn’t for all these people and others who contribute to the lively discussions on the mailing list, this project probably wouldn’t have got anywhere.

Last but not least, a big thank you goes to Chris Lattner and the entire LLVM team. LLVM really changed the game for us compiler writers, as we can now stop worrying about all the nitty-gritty details of code generation and concentrate on the design and implementation of the programming language at hand.
1.16 Copying

(The following explanations are not legal advice. Please read the full text of the licenses and consult qualified professional counsel for an interpretation of the license terms as they apply to you.)

Pure comes with a fairly liberal license which lets you distribute your own Pure programs and extensions under a license of your choice and permits linking of commercial applications against the Pure runtime and the Pure standard library without requiring special permission. The Pure interpreter (the *pure* main program), the Pure runtime library (*libpure*) and the Pure standard library (the Pure scripts in the *lib* folder distributed with the software) are distributed as free software, and you are welcome to modify and redistribute them under the appropriate license terms, as detailed below.

The *Pure interpreter* is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

The *Pure runtime library* and the *Pure standard library* are also free software: you can redistribute them and/or modify them under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

Pure is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

One thing to note here is that the interpreter program is distributed under the GNU General Public License and is thus subject to stricter license terms than the runtime library and the standard library which are licensed under the GNU Lesser General Public License. The main reason for these conditions is that the interpreter program includes support for the readline library which is GPL-licensed software. If this is a problem for your application then you’re welcome to use *pure_norl.c* instead. This is a readline-free replacement for the interpreter main program included in the distribution, which is licensed under a 3-clause BSD-style license.

Please see the GNU General Public License and the GNU Lesser General Public License for the precise license terms. You can also find the license conditions in the COPYING and COPYING.LESSER files accompanying the software. Also, please see the source code for the copyright and license notes pertaining to individual source files which are part of this software.

Third party software licensing notes:

Pure uses LLVM as its compiler backend. LLVM is under Copyright (c) 2003-2016 by the University of Illinois at Urbana-Champaign, and is licensed under a 3-clause BSD-style license, please read COPYING.LLVM included in the distribution for the exact licensing terms. You can also find the LLVM license at the LLVM website.

Pure Library Manual

Version 0.68, August 21, 2019
Albert Gräf <aggraef@gmail.com>
Copyright (c) 2009-2017 by Albert Gräf. This document is available under the GNU Free
Documentation License.

This manual describes the operations in the standard Pure library, including the prelude and
the other library modules which come bundled with the interpreter.

There is a companion to this manual, The Pure Manual which describes the Pure language
and the operation of the Pure interpreter.

2.1 Prelude

The prelude defines the basic operations of the Pure language. This includes the basic
arithmetic and logical operations, string, list and matrix functions, as well as the support
operations required to implement list and matrix comprehensions. The string, matrix and
record operations are in separate modules strings.pure, matrices.pure and records.pure, the
primitive arithmetic and logical operations can be found in primitives.pure. Note that since
the prelude module gets imported automatically (unless the interpreter is invoked with the
\-\-no-\-prelude option), all operations discussed in this section are normally available in Pure
programs without requiring any explicit import declarations, unless explicitly noted other-
wise.

2.1.1 Constants and Operators

The prelude also declares a signature of commonly used constant and operator symbols.
This includes the truth values true and false.

\texttt{constant true} = 1
constant false = 0

These are actually just integers in Pure, but sometimes it’s convenient to refer to them using these symbolic constants.

In addition, the following special exception symbols are provided:

constructor failed_cond
constructor failed_match
constructor stack_fault
constructor malloc_error

These are the built-in exception values. failed_cond denotes a failed conditional in guard or if-then-else; failed_match signals a failed pattern match in lambda, case expression, etc.; stack_fault means not enough stack space (PURE_STACK limit exceeded); and malloc_error indicates a memory allocation error.

constructor bad_list_value x
constructor bad_tuple_value x
constructor bad_string_value x
constructor bad_matrix_value x

These denote value mismatches a.k.a. dynamic typing errors. They are thrown by some operations when they fail to find an expected value of the corresponding type.

constructor out_of_bounds

This exception is thrown by the index operator ! if a list, tuple or matrix index is out of bounds.

Here’s the list of predefined operator symbols. Note that the parser will automagically give unary minus the same precedence level as the corresponding binary operator.

infixl 1000 $$ ;     // sequence operator
infixr 1100 $ ;     // right-associative application
infixr 1200 , ;     // pair (tuple)
infix 1300 => ;     // key=>value pairs ("hash rocket")
infix 1400 .. ;     // arithmetic sequences
infixr 1500 || ;     // logical or (short-circuit)
infixr 1600 && ;     // logical and (short-circuit)
prefix 1700 ~ ;     // logical negation
infix 1800 < > <= >= == ~= ;     // relations
infix 1800 === ~== ;     // syntactic equality
infixr 1900 : ;     // list cons
infix 2000 +: <: ;     // complex numbers (cf. math.pure)
infix 2100 << >> ;     // bit shifts
infix 2200 + - or ;     // addition, bitwise or
infix 2300 * / div mod and ;     // multiplication, bitwise and
infix 2300 % ;     // exact division (cf. math.pure)
prefix 2400 not ;     // bitwise not
infixr 2500 ^ ;     // exponentiation
prefix 2600 # ;     // size operator
infixl 2700 ! ! ! ;     // indexing, slicing
infixr 2800 . ;     // function composition
prefix 2900 ' ;     // quote
postfix 3000 & ;     // thunk
2.1.2 Prelude Types

Some additional type symbols are provided which can be used as type tags on the left-hand side of equations, see Type Tags in the Pure Manual.

```plaintext
type number
type complex
type real
type rational
type integer
type bool
```

Additional number types.

These types are defined in a purely syntactic way, by checking the builtin-type or the constructor symbol of a number. Some semantic number types can be found in the math module, see Semantic Number Predicates and Types.

- **integer** is the union of Pure’s built-in integer types, i.e., it comprises all `int` and `bigint` values. **bool** is a subtype of `int` which denotes just the normalized truth values 0 and 1 (a.k.a. `false` and `true`).

- **rational** and **complex** are the rational and complex types, while **real** is the union of the **double**, **integer** and **rational** types (i.e., anything that can represent a real number and be used for the real and imaginary parts of a **complex** number). Finally, **number** is the union of all numeric types, i.e., this type can be used to match any kind of number.

Note that the operations of the **rational** and **complex** types are actually defined in the math module which isn’t part of the prelude, so you have to import this module in order to do computations with these types of values. However, the type tags and constructors for these types are defined in the prelude so that these kinds of values can be parsed and recognized without having the math module loaded.

The prelude also provides a subtype of the built-in **string** type which represents single-character strings:

```plaintext
type char
```

A single character string. This matches any string value of length 1.

Lists and tuples can be matched with the following types:

```plaintext
type list
type rlist
```

The list and “proper” (or “recursive”) list types. Note that the former comprises both the empty list `[]` and all list nodes of the form `x:xs` (no matter whether the tail `xs` is a proper list value or not), whereas the latter only matches proper list values of the form `x1:...:xn:[]`. Thus the **list** type can be checked in O(1) time, while the **rlist** type is defined recursively and requires linear time (with respect to the size of the list) to be checked. This should be considered when deciding whether to use one or the other in a given situation; see Type Rules for further explanation.

```plaintext
type tuple
```

The type of all tuples, comprises the empty tuple `()` and all tuples `(x,xs)` with at least
two members. This is analogous to the list type above, but no “proper” tuple type is needed here since any tuple of this form is always a proper tuple.

There are some other, more specialized types representing various kinds of applications, function objects and other named entities. These are useful, in particular, for the definition of higher-order functions and for performing symbolic manipulations on unevaluated symbolic terms.

**type appl**
This type represents all unevaluated function or constructor applications of the form \(x\ y\). This comprises constructor terms and quoted or partial function applications.

**type function**
This type represents any term which may be called as a function. This may be a closure (global or local function, or a lambda function) which takes at least one argument, or a partial application of a closure to some arguments which is still “unsaturated”, i.e., expects some further arguments to be “ready to go”.

**type fun**
A named function object (global or local function, but not a partial application).

**type lambda**
An anonymous (lambda) function.

**type closure**
Any kind of function object (named function or lambda). This is the union of the fun and lambda types.

**type thunk**
This is a special kind of unevaluated parameterless function object used in lazy evaluation. See *Lazy Evaluation and Streams* in the Pure Manual.

**type var**
A free variable. This can be any kind of symbol that could in principle be bound to a value (excluding operator and nonfix symbols).

**type symbol**
Any kind of symbol (this also includes operator and nonfix symbols).

Corresponding type predicates are provided for all of the above, see Predicates. Some further types and predicates for matrices and records can be found under Matrix Inspection and Manipulation and Record Functions.

### 2.1.3 Basic Combinators

The prelude implements the following important function combinators.

\[ f \xrightarrow{\text{\$}} g \]
\[ f \xrightarrow{.} g \]

Like in Haskell, these denote right-associative application and function composition. They are also defined as macros so that saturated calls of them are eliminated automatically. Examples:
id x
cst x y
These are the customary identity and constant combinators from the combinatorial calculus:

> map id (1..5);
[1,2,3,4,5]
> map (cst 0) (1..5);
[0,0,0,0,0]

void x
This combinator is basically equivalent to cst (), but with the special twist that it is also defined as a macro optimizing the case of “throwaway” list and matrix comprehensions. This is useful if a comprehension is evaluated solely for its side effects. E.g.:

> using system;
> extern int rand();
> foo = void [printf "%d\n" rand | _ = 1..3];
> show foo
1714636915
1957747793
424238335
()

Note that the above list comprehension is actually implemented using do (instead of map, which would normally be the case), so that the intermediate list value of the comprehension is never constructed. This is described in more detail in section Optimization Rules of the Pure Manual.

In addition, the prelude also provides the following combinators adopted from Haskell:

flip f
Swaps arguments of a binary function f, e.g.:

> map (flip (/) 2) (1..3);
[0.5,1.0,1.5]

This combinator is also used by the compiler to implement right operator sections, which allows you to write the above simply as:

> map (/2) (1..3);
[0.5,1.0,1.5]

curry f
Turns a function f expecting a pair of values into a curried function of two arguments:
> using system;
> dowith (curry (printf "%d: %g

")) (0..2) [0.0,2.718,3.14];
  0: 0
  1: 2.718
  2: 3.14
()

uncurry f
The inverse of curry. Turns a curried function f expecting two arguments into a function processing a single pair argument:
> map (uncurry (*)) [(2,3),(4,5),(6,7)];
[6,20,42]
curry3 f
uncurry3 f
These work analogously, but are used to convert between ternary curried functions and functions operating on triples.
fix f
This is the (normal order) fixed point combinator which allows you to create recursive anonymous functions. It takes another function f as its argument and applies f to fix f itself:
> let fact = fix (\f n -> if n<=0 then 1 else n*f (n-1));
> map fact (1..5);
[1,2,6,24,120]
See Fixed point combinator at Wikipedia for an explanation of how this magic works. Just like in Haskell, fix can be used to produce least fixed points of arbitrary functions. For instance:
> fix (cst bar);
bar
> let xs = fix (1:);
> xs;
1:#<thunk 0x7fe537fe2f90>
> xs!!(0..10);
[1,1,1,1,1,1,1,1,1,1,1]

2.1.4 Lists and Tuples
The prelude defines the list and tuple constructors, as well as equality and inequality on these structures. It also provides a number of other useful basic operations on lists and tuples. These are all described below.
constructor []
constructor ()
    Empty list and tuple.
constructor x : y
constructor \( x \), \( y \)

List and tuple constructors. These are right-associative in Pure.

Lists are the usual right-recursive aggregates of the form \( x:xs \), where \( x \) denotes the head and \( xs \) the tail of the list, pretty much the same as in Lisp or Prolog except that they use a Haskell-like syntax. In contrast to Haskell, list concatenation is denoted ‘+’ (see below), and lists may contain an arbitrary mixture of arguments, i.e., they are fully polymorphic:

\[
\begin{align*}
\texttt{> 1:2:3:[]} &; \\
& \{1,2,3\} \\
\texttt{> [1,2,3]+[u,v,w]+[3.14]} &; \\
& \{1,2,3,u,v,w,3.14\}
\end{align*}
\]

Lists are eager in Pure by default, but they can also be made lazy (in the latter case they are also called streams). This is accomplished by turning the tail of a list into a “thunk” (a.k.a. “future”) which defers evaluation until the list tail is actually needed, see section Lazy Evaluation and Streams in the Pure Manual. For instance, an infinite arithmetic sequence (see below) will always produce a list with a thunked tail:

\[
\begin{align*}
\texttt{> 1:3..inf} &; \\
1:#<\text{thunk } 0x7f696cd2dbd8>
\end{align*}
\]

Pure also distinguishes proper and improper lists. The former are always terminated by an empty list in the final tail and can thus be written using the conventional \([x_1,x_2,\ldots,x_n]\) syntax:

\[
\begin{align*}
\texttt{> 1:2:3:[]} &; \\
& \{1,2,3\}
\end{align*}
\]

In contrast, improper lists are terminated with a non-list value and can only be represented using the ‘:’ operator:

\[
\begin{align*}
\texttt{> 1:2:3} &; \\
1:2:3
\end{align*}
\]

These aren’t of much use as ordinary list values, but are frequently encountered as patterns on the left-hand side of an equation, where the final tail is usually a variable. Also note that technically, a lazy list is also an improper list (although it may expand to a proper list value as it is traversed).

Tuples work in a similar fashion, but with the special twist that the pairing constructor ‘,’ is associative (it always produces right-recursive pairs) and ‘(‘)’ acts as a neutral element on these constructs, so that ‘,’ ‘,’ and ‘(‘)’ define a complete monoid structure. Note that this means that ‘,’ ‘,’ is actually a “constructor with equations” since it obeys the laws \((x,y),z == x,(y,z)\) and \((),x == x,(()) == x\). Also note that there isn’t a separate operation for concatenating tuples, since the pairing operator already does this:

\[
\begin{align*}
\texttt{> (1,2,3),(10,9,8)} &; \\
1,2,3,10,9,8 \\
\texttt{> (),(a,b,c)} &; \\
a,b,c
\end{align*}
\]
This also implies that tuples are always flat in Pure and can’t be nested; if you need this, you should use lists instead. Also, tuples are always eager in Pure.

Some important basic operations on lists and tuples are listed below:

\[ x + y \]

List concatenation. This non-destructively appends the elements of \( y \) to \( x \).

\[
\begin{align*}
> \ [1,2,3]+[u,v,w]);
[1,2,3,u,v,w] \\
\end{align*}
\]

Note that this operation in fact just recurses into \( x \) and replaces the empty list marking the “end” of \( x \) with \( y \), as if defined by the following equations (however, the prelude actually defines this operation in a tail-recursive fashion):

\[
\begin{align*}
[] + ys &= ys; \\
(x:xs) + ys &= x : xs+ys; \\
\end{align*}
\]

To make this work, both operands should be proper lists, otherwise you may get somewhat surprising (but correct) improper list results like the following:

\[
\begin{align*}
> \ [1,2,3]+99; \\
1:2:3:99 \\
> (1:2:3)+33; \\
1:2:36 \\
\end{align*}
\]

This happens because Pure is dynamically typed and places no limits on ad hoc polymorphism. Note that the latter result is due to the fact that ‘+’ also denotes the addition of numbers, and the improper tail of the first operand is a number in this case, as is the second operand. Otherwise you might have got an unreduced instance of the ‘+’ operator instead.

\[ x == y \]

Equality and inequality of lists and tuples. These compare two lists or tuples by recursively comparing their members, so ‘==’ must be defined on the list or tuple members if you want to use these operations. Also note that these operations are inherently eager, so applying them to two infinite lists may take an infinite amount of time.

\[
\begin{align*}
> \ \text{reverse} \ [a,b,c] \ == \ [c,b,a]; \\
1 \\
> \ (a,b,c) \ == \ (); \\
0 \\
\end{align*}
\]

\[ \# x \]

List and tuple size. This operation counts the number of elements in a list or tuple:

\[
\begin{align*}
> \ #\{a,b,c\}; \\
3 \\
\end{align*}
\]
> #\(a, b, c\);
3

Please note that for obvious reasons this operation is inherently eager, so trying to compute the size of an infinite list will take forever.

\(x!i\)
Indexing of lists and tuples is always zero-based (i.e., indices run from 0 to \(#x-1\)), and an exception will be raised if the index is out of bounds:

> [1,2,3]!2;
3
> [1,2,3]!4;
<stdin>, line 34: unhandled exception 'out_of_bounds' while evaluating ' [1,2,3]!4'

\(x!!\) is
The slicing operation takes a list or tuple and a list of indices and returns the list or tuple of the corresponding elements, respectively. Indices which are out of the valid range are silently ignored:

> (1..5)!![3..10];
[4,5]
> (1,2,3,4,5)!![3..10];
4,5

The case of contiguous index ranges, as shown above, is optimized so that it always works in linear time, see Slicing below for details. But indices can actually be specified in any order, so that you can retrieve any permutation of the members, also with duplicates. E.g.:

> (1..5)!![2,4,4,1];
[3,5,5,2]

This is less efficient than the case of contiguous index ranges, because it requires repeated traversals of the list for each index. For larger lists you should hence use vectors or matrices instead, to avoid the quadratic complexity.

\(x..y\)
Arithmetic sequences. Note that the Pure syntax differs from Haskell in that there are no brackets around the construct and a step width is indicated by specifying the first two elements as \(x:y\) instead of \(x,y\).

> 1..5;
[1,2,3,4,5]
> 1:3..11;
[1,3,5,7,9,11]

To prevent unwanted artifacts due to rounding errors, the upper bound in a floating point sequence is always rounded to the nearest grid point:
> 0.0:0.1..0.29;  
[0.0,0.1,0.2,0.3]  
> 0.0:0.1..0.31;  
[0.0,0.1,0.2,0.3]

Last but not least, you can specify infinite sequences with an infinite upper bound (inf or -inf):

> 1:3..inf;  
1:0x7f696cd2dbd8>  
> -1:-3..-inf;  
-1:0x7f696cd2fde8>

The lower bounds of an arithmetic sequence must always be finite.

**null x**

Test for the empty list and tuple.

> null [];  
1  
> null (a,b,c);  
0

**reverse x**

Reverse a list or tuple.

> reverse (1..5);  
[5,4,3,2,1]  
> reverse (a,b,c);  
(c,b,a)

In addition, the prelude provides the following conversion operations.

**list x**

Convert between (finite) lists and tuples.

> tuple (1..5);  
1,2,3,4,5  
> list (a,b,c);  
[a,b,c]

The list function can be used to turn a finite lazy list into an eager one:

> list $ take 10 (-1:-3..-inf);  
[-1,-3,-5,-7,-9,-11,-13,-15,-17,-19]

You can also achieve the same effect somewhat more conveniently by slicing a finite part from a stream:

> (-1:-3..inf)!!(0..9);  
[-1,-3,-5,-7,-9,-11,-13,-15,-17,-19]

Conversely, it is also possible to convert an (eager) list to a lazy one (a stream).
stream x
   Convert a list to a stream.
> stream (1..10);
  1:<thunk 0x7fe537fe2b58>

This might appear a bit useless at first sight, since all elements of the stream are in fact already known. However, this operation then allows you to apply other functions to the list and have them evaluated in a lazy fashion.

### 2.1.5 Slicing

Indexing and slicing are actually fairly general operations in Pure which are used not only in the context of lists and tuples, but for any type of container data structure which can be “indexed” in some way. Other examples in the standard library are the array and dict containers.

The prelude therefore implements slicing in a generic way, so that it works with any kind of container data structure which defines ‘!’ in such a manner that it throws an exception when the index is out of bounds. It also works with any kind of index container that implements the catmap operation.

The prelude also optimizes the case of contiguous integer ranges so that slices like `xs!!(i..j)` are computed in linear time if possible. This works, in particular, with lists, strings and matrices.

Moreover, the prelude includes some optimization rules and corresponding helper functions to optimize the most common cases at compile time, so that the index range is never actually constructed. To these ends, the slicing expression `xs!!(i..j)` is translated to a call `subseq` on `xs i j` of the special `subseq` function:

**subseq x ij**
   If `x` is a list, matrix or string, and `i` and `j` are int values, compute the slice `xs!!(i..j)` in the most efficient manner possible. This generally avoids constructing the index list `i..j`. Otherwise `i..j` is computed and `subseq` falls back to the `slice` function below to compute the slice in the usual way.

**slice x ys**
   Compute the slice `x!!ys` using the standard slicing operation, without any special compile time tricks. (Runtime optimizations are still applied if possible.)

You can readily see the effects of this optimization by running the slicing operator against `slice`:

> let xs = 1..1000000;
> stats -m
> #slice xs (100000..299990);
199991
0.34s, 999957 cells
> #xs!!(100000..299990);
199991
0.14s, 399984 cells
Even more drastic improvements in both running time and memory usage can be seen in the case of matrix slices:

```haskell
> let x = rowvector xs;
> #slice x (100000..299990);
199991
0.19s, 599990 cells
> #x!!(100000..299990);
199991
0s, 10 cells
```

### 2.1.6 Hash Pairs

The prelude provides another special kind of pairs called “hash pairs”, which take the form `key=>value`. These are used in various contexts to denote key-value associations. The only operations on hash pairs provided by the prelude are equality testing (which recursively compares the components) and the functions `key` and `val`:

**constructor** `x => y`

- The hash pair constructor, also known as the “hash rocket”.

```haskell
x == y
x ~= y
```

Equality and inequality of hash pairs.

```haskell
> ("foo"=>99) == ("bar"=>99);
0
```

**key** `(x=>y)`

**val** `(x=>y)`

- Extract the components of a hash pair.

```haskell
> key ("foo"=>99), val ("foo"=>99);
"foo",99
```

Note that in difference to the tuple operator ‘,’ the hash rocket ‘=>’ is non-associative, so nested applications must be parenthesized, and `(x=>y)=>z` is generally not the same as `x=>(y=>z)`. Also note that ‘,’ has lower precedence than ‘=>’, so to include a tuple as key or value in a hash pair, the tuple must be parenthesized, as in "foo"=>(1,2) (whereas "foo"=>1,2 denotes a tuple whose first element happens to be a hash pair).

### 2.1.7 List Functions

This mostly comes straight from the Q prelude which in turn was based on the first edition of the Bird/Wadler book, and is very similar to what you can find in the Haskell prelude. Some functions have slightly different names, though, and of course everything is typed dynamically.
Common List Functions

any \( p \) \( x \)

- test whether the predicate \( p \) holds for any of the members of \( x \)

all \( p \) \( x \)

- test whether the predicate \( p \) holds for all of the members of \( x \)

cat \( x \)

- concatenate a list of lists

catmap \( f \) \( x \)

- convenience function which combines \( \text{cat} \) and \( \text{map} \); this is also used to implement list comprehensions

do \( f \) \( x \)

- apply \( f \) to all members of \( x \), like \( \text{map} \), but throw away all intermediate results and return ()

drop \( n \) \( x \)

- remove \( n \) elements from the front of \( x \)

dropwhile \( p \) \( x \)

- remove elements from the front of \( x \) while the predicate \( p \) is satisfied

filter \( p \) \( x \)

- return the list of all members of \( x \) satisfying the predicate \( p \)

foldl \( f \) \( a \) \( x \)

- accumulate the binary function \( f \) over all members of \( x \), starting from the initial value \( a \) and working from the front of the list towards its end

foldl1 \( f \) \( x \)

- accumulate the binary function \( f \) over all members of \( x \), starting from the value \( \text{head} x \) and working from the front of the list towards its end; \( x \) must be nonempty

foldr \( f \) \( a \) \( x \)

- accumulate the binary function \( f \) over all members of \( x \), starting from the initial value \( a \) and working from the end of the list towards its front

foldr1 \( f \) \( x \)

- accumulate the binary function \( f \) over all members of \( x \), starting from the value \( \text{last} x \) and working from the end of the list towards its front; \( x \) must be nonempty

head \( x \)

- return the first element of \( x \); \( x \) must be nonempty

index \( x \) \( x \)

- search for an occurrence of \( x \) in \( x \) and return the index of the first occurrence, if any, -1 otherwise

Note: This uses equality \( == \) to decide whether a member of \( x \) is an occurrence of \( x \), so \( == \) must have an appropriate definition on the list members.
init \( xs \)

return all but the last element of \( xs \); \( xs \) must be nonempty

last \( xs \)

return the last element of \( xs \); \( xs \) must be nonempty

listmap \( f \) \( xs \)

convenience function which works like map, but also deals with matrix and string arguments while ensuring that the result is always a list; this is primarily used to implement list comprehensions

map \( f \) \( xs \)

apply \( f \) to each member of \( xs \)

scanl \( f \) \( a \) \( xs \)

accumulate the binary function \( f \) over all members of \( xs \), as with foldl, but return all intermediate results as a list

scanl1 \( f \) \( xs \)

accumulate the binary function \( f \) over all members of \( xs \), as with foldl1, but return all intermediate results as a list

scanr \( f \) \( a \) \( xs \)

accumulate the binary function \( f \) over all members of \( xs \), as with foldr, but return all intermediate results as a list

scanr1 \( f \) \( xs \)

accumulate the binary function \( f \) over all members of \( xs \), as with foldr1, but return all intermediate results as a list

sort \( p \) \( xs \)

Sorts the elements of the list \( xs \) in ascending order according to the given predicate \( p \), using the C qsort function. The predicate \( p \) is invoked with two arguments and should return a truth value indicating whether the first argument is “less than” the second. (An exception is raised if the result of a comparison is not a machine integer.)

\[
> \text{sort (\( \geq \)) \( (1..10) \);} \\
[10,9,8,7,6,5,4,3,2,1] \\
> \text{sort (\( < \)) ans;} \\
[1,2,3,4,5,6,7,8,9,10]
\]

tail \( xs \)

return all but the first element of \( xs \); \( xs \) must be nonempty

take \( n \) \( xs \)

take \( n \) elements from the front of \( xs \)

takewhile \( p \) \( xs \)

take elements from the front of \( xs \) while the predicate \( p \) is satisfied
List Generators

Some useful (infinite) list generators, as well as some finite (and eager) variations of these. The latter work like a combination of take or takewhile and the former, but are implemented directly for better efficiency.

**cycle** \(xs\)
- cycles through the elements of the nonempty list \(xs\), ad infinitum

**cyclen** \(n \ xs\)
- eager version of cycle, returns the first \(n\) elements of cycle \(xs\)

**iterate** \(f \ x\)
- returns the stream containing \(x, f \ x, f \ (f \ x), \ldots\), ad infinitum

**iteraten** \(n \ f \ x\)
- eager version of iterate, returns the first \(n\) elements of iterate \(f \ x\)

**iterwhile** \(p \ f \ x\)
- another eager version of iterate, returns the list of all elements from the front of iterate \(f \ x\) for which the predicate \(p\) holds

**repeat** \(x\)
- returns an infinite stream of \(x\)

**repeatn** \(n \ x\)
- eager version of repeat, returns a list with \(n\) \(x\)s

Zip and Friends

**unzip** \(xys\)
- takes a list of pairs to a pair of lists of corresponding elements

**unzip3** \(xyzs\)
- \(unzip\) with triples

**zip** \(xs \ ys\)
- return the list of corresponding pairs \((x, y)\) where \(x\) runs through the elements of \(xs\) and \(y\) runs through the elements of \(ys\)

**zip3** \(xs \ ys \ zs\)
- \(zip\) with three lists, returns a list of triples

**zipwith** \(f \ xs \ ys\)
- apply the binary function \(f\) to corresponding elements of \(xs\) and \(ys\)

**zipwith3** \(f \ xs \ ys \ zs\)
- apply the ternary function \(f\) to corresponding elements of \(xs, ys\) and \(zs\)

Pure also has the following variations of zipwith and zipwith3 which throw away all intermediate results and return the empty tuple (\(\)\). That is, these work like do but pull arguments from two or three lists, respectively:
**dowith** \( f \) \( xs \) \( ys \)
apply the binary function \( f \) to corresponding elements of \( xs \) and \( ys \), return \( () \)

**dowith3** \( f \) \( xs \) \( ys \) \( zs \)
apply the ternary function \( f \) to corresponding elements of \( xs \), \( ys \) and \( zs \), return \( () \)

### 2.1.8 String Functions

Pure strings are null-terminated character strings encoded in UTF-8, see the Pure Manual for details. The prelude provides various operations on strings, including a complete set of list-like operations, so that strings can be used mostly as if they were lists, although they are really implemented as C character arrays for reasons of efficiency. Pure also has some powerful operations to convert between Pure expressions and their string representation, see Eval and Friends for those.

**Basic String Functions**

\( s + t \)
\( s ! i \)
\( s !!} is \)

String concatenation, indexing and slicing works just like with lists:

```>
> "abc"++"xyz";
"abcxyz"
> let s = "The quick brown fox jumps over the lazy dog.";
> s!5;
"u"
> s!!(20..24);
"jumps"
```

\( \text{null } s \)
\( \# s \)

Checking for empty strings and determining the size of a string also works as expected:

```>
> null "";
1
> null s;
0
> \# s;
44
```

\( s == t \)
\( s =\approx t \)
\( s <= t \)
\( s >= t \)
\( s < t \)
\( s > t \)

String equality and comparisons. This employs the usual lexicographic order based on the (UTF-8) character codes.
You can search for the location of a substring in a string, and extract a substring of a given length:

\texttt{index \textit{s u}}

Returns the (zero-based) index of the first occurrence of the substring \textit{u} in \textit{s}, or -1 if \textit{u} is not found in \textit{s}.

\texttt{substr \textit{s i n}}

Extracts a substring of (at most) \textit{n} characters at position \textit{i} in \textit{s}. This takes care of all corner cases, adjusting index and number of characters so that the index range stays confined to the source string.

Example:
\begin{verbatim}
> index s "jumps";
20
> substr s 20 10;
"jumps over"
\end{verbatim}

Note that Pure doesn’t have a separate type for individual characters. Instead, these are represented as strings \textit{c} containing exactly one (UTF-8) character (i.e., \textit{#c==1}). It is possible to convert such single character strings to the corresponding integer character codes, and vice versa:

\texttt{ord \textit{c}}

Ordinal number of a single character string \textit{c}. This is the character’s code point in the Unicode character set.

\texttt{chr \textit{n}}

Converts an integer back to the character with the corresponding code point.

In addition, the usual character arithmetic works, including arithmetic sequences of characters, so that you can write stuff like the following:

\begin{verbatim}
> "a"."A";
32
> "u".-32;
"y"
> "a".."k";
["a","b","c","d","e","f","g","h","i","j","k"]
\end{verbatim}

For convenience, the prelude provides the following functions to convert between strings and lists (or other aggregates) of characters.

\texttt{chars \textit{s}}

\section*{2.1.8 String Functions}
**Pure Language and Library Documentation, Release 0.68**

- **list** `s`
  Convert a string `s` to a list of characters.

- **tuple** `s`
- **matrix** `s`
  Convert a string `s` to a tuple or (symbolic) matrix of characters, respectively.

- **strcat** `xs`
  Concatenate a list `xs` of strings (in particular, this converts a list of characters back to a string).

- **string** `xs`
  Convert a list, tuple or (symbolic) matrix of strings to a string. In the case of a list, this is synonymous with **strcat**, but it also works with the other types of aggregates.

For instance:

```>
> list "abc";
["a","b","c"]

> string ("a"..'z");
"abcdefghijklmnopqrstuvwxyz"
```

The following functions are provided to deal with strings of “tokens” separated by a given delimiter string.

- **split** `delim s`
  Splits `s` into a list of substrings delimited by `delim`.

- **join** `delim xs`
  Joins the list of strings `xs` to a single string, interpolating the given `delim` string.

Example:

```>
> let xs = split " " s; xs;
["The","quick","brown","fox","jumps","over","the","lazy","dog."]

> join ":" xs;
```

We mention in passing here that more elaborate string matching, splitting and replacement operations based on regular expressions are provided by the system module, see [Regex Matching](#).

If that isn’t enough already, most generic list operations carry over to strings in the obvious way, treating the string like a list of characters. (Polymorphic operations such as **map**, which aren’t guaranteed to yield string results under all circumstances, will actually return lists in that case, so you might have to apply **string** explicitly to convert these back to a string.) For instance:

```>
> filter (>="k") s;
"qukrownoxumpsorvrlzyo"

> string $ map pred "ibm";
"hal"
```

List comprehensions can draw values from strings, too:
> string [x+1 | x="HAL"];  
"IBM"

**Low-Level Operations**

The following routines are provided by the runtime to turn raw C char* pointers (also called byte strings in Pure parlance, to distinguish them from Pure’s “cooked” UTF-8 string values) into corresponding Pure strings. Normally you don’t have to worry about this, because the C interface already takes care of the necessary marshalling, but in some low-level code these operations are useful. Also note that here and in the following, the cstring routines also convert the string between the system encoding and Pure’s internal UTF-8 representation.

- **string s cstring s**
  - Convert a pointer s to a Pure string. s must point to a null-terminated C string. These routines take ownership of the original string value, assuming it to be malloced, so you should only use these for C strings which are specifically intended to be freed by the user.

- **string_dup s cstring_dup s**
  - Convert a pointer s to a Pure string. Like above, but these functions take a copy of the string, leaving the original C string untouched.

The reverse transformations are also provided. These take a Pure string to a byte string (raw char*).

- **byte_string s byte_cstring s**
  - Construct a byte string from a Pure string s. The result is a raw pointer object pointing to the converted string. The original Pure string is always copied (and, in the case of byte_cstring, converted to the system encoding). The resulting byte string is a malloced pointer which can be used like a C char*, and has to be freed explicitly by the caller when no longer needed.

It is also possible to convert Pure string lists or symbolic vectors of strings to byte string vectors and vice versa. These are useful if you need to pass an argv-like string vector (i.e., a char** or char*[]) to C routines. The computed C vectors are malloced pointers which have an extra NULL pointer as the last entry, and should thus be usable for almost any purpose which requires such a string vector in C. They also take care of garbage-collecting themselves. The original string data is always copied. As usual, the cstring variants do automatic conversions to the system encoding.

- **byte_string_pointer xs byte_cstring_pointer xs**
  - Convert a list or vector of Pure strings to a C char**.

- **string_list n p cstring_list n p**
  - Convert a C char** to a list of Pure strings.
string_vector n p
cstring_vector n p

Convert a C char** to a symbolic vector of Pure strings.

Note that the back conversions take an additional first argument which denotes the number of strings to retrieve. If you know that the vector is NULL-terminated then this can also be an infinite value (inf) in which case the number of elements will be figured out automatically. Processing always stops at the first NULL pointer encountered.

Also note that, as of version 0.45, Pure has built-in support for passing argv-style vectors as arguments by means of the char** and void** pointer types. However, the operations provided here are more general in that they allow you to both encode and decode such values in an explicit fashion. This is useful, e.g., for operations like getopt which may mutate the given char** vector.

If you have getopt in your C library, you can try the following example. First enter these definitions:

```pure
extern int getopt(int argc, char **argv, char *optstring);
optind = get_int $ addr "optind";
optarg = cstring_dup $ get_pointer $ addr "optarg";
```

Now let’s run getopt on a byte string vector constructed from an argument vector (which includes the “program name” in the first element):

```pure
> let args = byte_cstring_pointer {"progname","boo","-n","-tfoo","bar"};
> getopt 5 args "nt: ", optarg;
110,#<pointer 0x0>
> getopt 5 args "nt: ", optarg;
116,"foo"
> getopt 5 args "nt: ", optarg;
-1,#<pointer 0x0>
```

Note that 110 and 116 are the character codes of the option characters n and t, where the latter option takes an argument, as returned by optarg. Finally, getopt returns -1 to indicate that there are no more options, and we can retrieve the current optind value and the mutated argument vector to see which non-option arguments remain to be processed, as follows:

```pure
> optind, cstring_vector 5 args;
3,{"progname","-n","-tfoo","boo","bar"}
```

It is now an easy exercise to design your own high-level wrapper around getopt to process command line arguments in Pure. However, this isn’t really necessary since the Pure library already offers such an operation which doesn’t rely on any special system functions, see Option Parsing in the System Interface section.

### 2.1.9 Matrix Functions

Matrices are provided as an alternative to the list and tuple aggregates which provide constant time access to their members and are tailored for use in numeric computations.
# x
\textbf{dim} \textit{x}

Determine the size of a matrix (number of elements) and its dimensions (number of rows and columns).

\begin{verbatim}
> let x = {1,2,3;4,5,6}; #x;
6
> dim x;
2,3
\end{verbatim}

\textbf{null}

Check for empty matrices. Note that there are various kinds of these, as a matrix may have zero rows or columns, or both.

\begin{verbatim}
x == y
x ~= y
\end{verbatim}

Matrix equality and inequality. These check the dimensions and the matrix elements for equality:

\begin{verbatim}
> x == transpose x;
0
\end{verbatim}

\textbf{x ! i}

\textbf{x !! is}

Indexing and slicing.

Indexing and slicing employ the standard Pure operators ‘!’ and ‘!!’. They work pretty much like in MATLAB and Octave, but note that Pure matrices are in row-major order and the indices are zero-based. It is possible to access elements with a one-dimensional index (in row-major order):

\begin{verbatim}
> x!3;
4
\end{verbatim}

Or you can specify a pair of row and column index:

\begin{verbatim}
> x!(1,0);
4
\end{verbatim}

Slicing works accordingly. You can either specify a list of (one- or two-dimensional) indices, in which case the result is always a row vector:

\begin{verbatim}
> x!!(2..5);
\{3,4,5,6\}
\end{verbatim}

Or you can specify a pair of row and column index lists:

\begin{verbatim}
> x!!(0..1,1..2);
\{2,3;5,6\}
\end{verbatim}

The following abbreviations are provided to grab a slice from a row or column:
As in the case of lists, matrix slices are optimized to handle cases with contiguous index ranges in an efficient manner, see Slicing for details. To these ends, the helper functions subseq and subseq2 are defined to handle the necessary compile time optimizations.

Most of the generic list operations are implemented on matrices as well, see Common List Functions. Hence operations like map and zipwith work as expected:

```
> map succ [1,2,3;4,5,6];
{2,3,4;5,6,7}
> zipwith (+) {1,2,3;4,5,6} {1,0,1;0,2,0};
{2,2,4;4,7,6}
```

The matrix module also provides a bunch of other specialized matrix operations, including all the necessary operations for matrix comprehensions. We briefly summarize the most important operations below; please refer to matrices.pure for all the gory details. Also make sure you check Matrices and Vectors in the Pure Manual for some more examples, and the Record Functions section for an implementation of records using symbolic vectors.

### Matrix Construction and Conversions

**matrix xs**

This function converts a list or tuple to a corresponding matrix. matrix also turns a list of lists or matrices specifying the rows of the matrix to the corresponding rectangular matrix; otherwise, the result is a row vector. (In the former case, matrix may throw a bad_matrix_value exception in case of dimension mismatch, with the offending submatrix as argument.)

```
> matrix [1,2,3];
{1,2,3}
> matrix [[1,2,3],[4,5,6]];
{1,2,3;4,5,6}
```

**rowvector xs**

**colvector xs**

**vector xs**

The rowvector and colvector functions work in a similar fashion, but expect a list, tuple or matrix of elements and always return a row or column vector, respectively (i.e., a $1 \times n$ or $n \times 1$ matrix, where $n$ is the size of the converted aggregate). Also, the vector function is a synonym for rowvector. These functions can also be used to create recursive (symbolic) matrix structures of arbitrary depth, which provide a nested array data structure with efficient (constant time) element access.

```
> rowvector [1,2,3];
{1,2,3}
> colvector [1,2,3];
```
vector \([1,2,3],[4,5,6]\);

Note that for convenience, there’s also an alternative syntax for entering nested vectors more easily, see the description of the non-splicing vector brackets below for details.

**rowvectorseq** \(x\ y\ \text{step}

**colvectorseq** \(x\ y\ \text{step}

**vectorseq** \(x\ y\ \text{step}

With these functions you can create a row or column vector from an arithmetic sequence. Again, **vectorseq** is provided as a synonym for **rowvectorseq**. These operations are optimized for the case of int and double ranges.

```plaintext
> rowvectorseq 0 10 1;
\{0,1,2,3,4,5,6,7,8,9,10\}
> colvectorseq 0 10 1;
\{0;1;2;3;4;5;6;7;8;9;10\}
> vectorseq 0.0 0.9 0.1;
\{0.0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9\}
```

The prelude also contains some optimization rules which translate calls to **vector** et al on arithmetic sequences to the corresponding calls to **vectorseq** et al, such as:

```plaintext
def vector (n1:n2..m) = vectorseq n1 m (n2-n1);
def vector (n..m) = vectorseq n m 1;
```

Example:

```plaintext
> foo = vector (1..10);
> bar = vector (0.0:0.1..0.9);
> show foo bar
bar = vectorseq 0.0 0.9 0.1;
foo = vectorseq 1 10 1;
> foo; bar;
\{1,2,3,4,5,6,7,8,9,10\}
\{0.0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9\}
```

Please note that these optimization rules assume that basic arithmetic works with the involved elements, which may give you trouble if you try to use **vector** et al with exotic kinds of user-defined arithmetic sequences. To disable them, simply run the interpreter with the option `--disable vectorseq-opt`.

**dmatrix** \(xs\)

**cmatrix** \(xs\)

**imatrix** \(xs\)

**smatrix** \(xs\)

These functions convert a list or matrix to a matrix of the corresponding type (integer, double, complex or symbolic). If the input is a list, the result is always a row vector; this is usually faster than the **matrix** and **vector** operations, but requires that the elements already are of the appropriate type.
> imatrix [1,2,3];
    {1,2,3}
> dmatrix {1,2,3;4,5,6};
    {1.0,2.0,3.0;4.0,5.0,6.0}

In addition, these functions can also be invoked with either an int n or a pair (n,m) of ints as argument, in which case they construct a zero rowvector or matrix with the corresponding dimensions.

> imatrix 3;
    {0,0,0}
> imatrix (2,3);
    {0,0,0;0,0,0}

list x
list2 x
tuple x

These convert a matrix back to a flat list or tuple. The list2 function converts a matrix to a list of lists (one sublist for each row of the matrix).

> tuple {1,2,3;4,5,6};
    1,2,3,4,5,6
> list {1,2,3;4,5,6};
    {1,2,3,4,5,6}
> list2 {1,2,3;4,5,6};
    {{1,2,3},{4,5,6}}
> list2 {1,2,3};
    {[1,2,3]}

In addition, the following special syntax is provided as a shorthand notation for nested vector structures:

macro { | x, y, z, ... | }

Non-splicing vector brackets. These work like {x,y,z,...}, but unlike these they will not splice submatrices in the arguments x,y,z,... So they work a bit like quoted vectors '{x,y,z,...}, but the arguments x,y,z,... will be evaluated as usual.

The non-splicing vector brackets provide a convenient shorthand to enter symbolic vector values which may contain other vectors or matrices as components. For instance, note how the ordinary matrix brackets combine the column subvectors in the first example below to a 3x2 matrix, while the non-splicing brackets in the second example create a 1x2 row vector with the column vectors as members instead:

> {{1;2;3},{4;5;6}};
    {1,4;2,5;3,6}
> {{|{1;2;3},{4;5;6}|}};
    {{1;2;3},{4;5;6}}

The second example works like a quoted matrix expression such as '{{{1;2;3},{4;5;6}}}, but the non-splicing brackets also evaluate their arguments.
The \{ | \} brackets can be nested. Examples:

\[
> \{(1,3),2*3\},\{(3,4)\}\};
\]

Also note that the \{ | \} brackets only produce row vectors, but you can just transpose the result if you need a column vector instead:

\[
> transpose \{(1;2;3),(4;5;6)\};
\]

Finally, note that the notation \{ | \} without any arguments is not supported, simply write \{} for the empty vector instead.

## Matrix Inspection and Manipulation

**type dmatrix**

**type cmatrix**

**type imatrix**

**type smatrix**

**type nmatrix**

Convenience types for the different subtypes of matrices (double, complex, int, symbolic and numeric, i.e., non-symbolic). These can be used as type tags on the left-hand side of equations to match specific types of matrices.

**dmatrixp x**

**cmatrixp x**

**imatrixp x**

**smatrixp x**

**nmatrixp x**

Corresponding predicates to check for different kinds of matrices.

**vectorp x**

**rowvectorp x**

**colvectorp x**

Check for different kinds of vectors (these are just matrices with one row or column).

**stride x**

The stride of a matrix denotes the real row size of the underlying C array, see the description of the `pack` function below for further details. There’s little use for this value in Pure, but it may be needed when interfacing to C.

**subseq x i j**
subseq2 \( x \) \( i \) \( j \) \( k \) \( l \)
Helper functions to optimize matrix slices, see Slicing for details. subseq2 is a special version of subseq which is used to optimize the case of 2-dimensional matrix slices \( xs!!(i..j,k..l) \).

row \( x \) \( i \)
col \( x \) \( i \)
Extract the \( i \)th row or column of a matrix.

rows \( x \)
cols \( x \)
Return the list of all rows or columns of a matrix.

diag \( x \)
subdiag \( x \) \( k \)
supdiag \( x \) \( k \)
Extract (sub-,super-) diagonals from a matrix. Sub- and super-diagonals for \( k=0 \) return the main diagonal. Indices for sub- and super-diagonals can also be negative, in which case the corresponding super- or sub-diagonal is returned instead. In each case the result is a row vector.

submat \( x \) \( (i,j) \) \( (n,m) \)
Extract a submatrix of a given size at a given offset. The result shares the underlying storage with the input matrix (i.e., matrix elements are not copied) and so this is a comparatively cheap operation.

rowcat \( xs \)
colcat \( xs \)
Construct matrices from lists of rows and columns. These take either scalars or submatrices as inputs; corresponding dimensions must match. rowcat combines submatrices vertically, like \( \{x;y\} \); colcat combines them horizontally, like \( \{x,y\} \). Note: Like the built-in matrix constructs, these operations may throw a bad_matrix_value exception in case of dimension mismatch.

matcat \( xs \)
Construct a matrix from a (symbolic) matrix of other matrices and/or scalars. This works like a combination of rowcat and colcat, but draws its input from a matrix instead of a list of matrices, and preserves the overall layout of the “host” matrix. The net effect is that the host matrix is flattened out. If all elements of the input matrix are scalars already, the input matrix is returned unchanged.

rowcatmap \( f \) \( xs \)
colcatmap \( f \) \( xs \)
rowmap \( f \) \( xs \)
colmap \( f \) \( xs \)
Various combinations of rowcat, colcat and map. These are used, in particular, for implementing matrix comprehensions.

diagmat \( x \)
subdiagmat \( x \) \( k \)
**supdiagmat** \(x\ k\)
Create a (sub-,super-) diagonal matrix from a row vector \(x\) of size \(n\). The result is always a square matrix with dimension \((n+k,n+k)\), which is of the same matrix type (double, complex, int, symbolic) as the input and has the elements of the vector on its \(k\)th sub- or super-diagonal, with all other elements zero. A negative value for \(k\) turns a sub- into a super-diagonal matrix and vice versa.

**re** \(x\)
**im** \(x\)
**conj** \(x\)
Extract the real and imaginary parts and compute the conjugate of a numeric matrix.

**pack** \(x\)
**packed** \(x\)
Pack a matrix. This creates a copy of the matrix which has the data in contiguous storage. It also frees up extra memory if the matrix was created as a slice from a bigger matrix (see **submat** above) which has since gone the way of the dodo. The **packed** predicate can be used to verify whether a matrix is already packed. Note that even if a matrix is already packed, **pack** will make a copy of it anyway, so **pack** also provides a quick way to copy a matrix, e.g., if you want to pass it as an input/output parameter to a GSL routine.

**redim** \((n,m)\) \(x\)
**redim** \(n\) \(x\)
Change the dimensions of a matrix without changing its size. The total number of elements must match that of the input matrix. Reuses the underlying storage of the input matrix if possible (i.e., if the matrix is **packed**). You can also redim a matrix to a given row size \(n\). In this case the row size must divide the total size of the matrix.

**sort** \(p\) \(x\)
Sorts the elements of a matrix (non-destructively, i.e., without changing the original matrix) according to the given predicate, using the C `qsort` function. This works exactly the same as with lists (see Common List Functions), except that it takes and returns a matrix instead of a list. Note that the function sorts all elements of the matrix in one go (regardless of the dimensions), as if the matrix was a single big vector. The result matrix has the same dimensions as the input matrix. Example:

```plaintext
> sort (<) {10,9;8,7;6,5};
{5,6;7,8;9,10}
```

If you’d like to sort the individual rows instead, you can do that as follows:

```plaintext
> sort_rows p = rowcat . map (sort p) . rows;
> sort_rows (<) {10,9;8,7;6,5};
{9,10;7,8;5,6}
```

Likewise, to sort the columns of a matrix:

```plaintext
> sort_cols p = colcat . map (sort p) . cols;
> sort_cols (<) {10,9;8,7;6,5};
{6,5;8,7;10,9}
```
Also note that the pure-gsl module provides an interface to the GSL routines for sorting numeric (int and double) vectors using the standard order. These will usually be much faster than `sort`, whereas `sort` is more flexible in that it also allows you to sort symbolic matrices and to choose the order predicate.

```plaintext
transpose x
   Transpose a matrix. Example:
   > transpose {1,2,3;4,5,6};
   {1,4;2,5;3,6}
```

```plaintext
rowrev x
colrev x
reverse x
   Reverse a matrix. `rowrev` reverses the rows, `colrev` the columns, `reverse` both dimensions.
```

### Pointers and Matrices

Last but not least, the matrix module also offers a bunch of low-level operations for converting between matrices and raw pointers. These are typically used to shovel around massive amounts of numeric data between Pure and external C routines, when performance and throughput is an important consideration (e.g., graphics, video and audio applications). The usual caveats concerning direct pointer manipulations apply.

```plaintext
pointer x
   Get a pointer to the underlying C array of a matrix. The data is not copied. Hence you have to be careful when passing such a pointer to C functions if the underlying data is non-contiguous; when in doubt, first use the `pack` function to place the data in contiguous storage, or use one of the matrix-pointer conversion routines below.
```

```plaintext
double_pointer p x
float_pointer p x
complex_pointer p x
complex_float_pointer p x
int64_pointer p x
int_pointer p x
short_pointer p x
byte_pointer p x
```

These operations copy the contents of a matrix to a given pointer and return that pointer, converting to the target data type on the fly if necessary. The given pointer may also be `NULL`, in which case suitable memory is malloced and returned; otherwise the caller must ensure that the memory pointed to by `p` is big enough for the contents of the given matrix. The source matrix `x` may be an arbitrary numeric matrix. In the case of `int64_pointer`, `x` may also be a symbolic matrix holding bigint values which are converted to 64 bit machine integers.

```plaintext
double_matrix (n,m) p
float_matrix (n,m) p
complex_matrix (n,m) p
```
These functions allow you to create a matrix from a pointer, copying the data and converting it from the source type on the fly if necessary. The result will be a numeric matrix of the appropriate type, except in the case of \texttt{int64\_matrix} where the result is a symbolic matrix consisting of bigint values. The source pointer \( p \) may also be \texttt{NULL}, in which case the new matrix is filled with zeros instead. Otherwise the caller must ensure that the pointer points to properly initialized memory big enough for the requested dimensions. The given dimension may also be just an integer \( n \) if a row vector is to be created.

These operations can be used to create a numeric matrix view of existing data, without copying the data. The data must be double, complex or int, the pointer must not be \texttt{NULL} and the caller must also ensure that the memory persists for the entire lifetime of the matrix object. The given dimension may also be just an integer \( n \) if a row vector view is to be created.

2.1.10 Record Functions

As of Pure 0.41, the prelude also provides a basic record data structure, implemented as symbolic vectors of key=>value pairs which support a few dictionary-like operations such as \texttt{member, insert} and indexing. Records may be represented as row, column or empty vectors (i.e., the number of rows or columns must be zero or one). They must be symbolic matrices consisting only of “hash pairs” key=>value, where the keys can be either symbols or strings. The values can be any kind of Pure data; in particular, they may themselves be records, so records can be nested.

The following operations are provided. Please note that all updates of record members are non-destructive and thus involve copying, which takes linear time (and space) and thus might be slow for large record values; if this is a problem then you should use dictionaries instead (cf. Dictionaries). Or you can create mutable records by using expression references (cf. Expression References) as values, which allow you to modify the data in-place. Element lookup (indexing) uses binary search on an internal index data structure and thus takes logarithmic time once the index has been constructed (which is done automatically when needed, or when calling \texttt{recordp} on a fresh record value).

Also note that records with duplicate keys are permitted; in such a case the following operations will always operate on the last entry for a given key.

\textbf{type record}

The record type. This is functionally equivalent to \texttt{recordp}, but can be used as a type tag on the left-hand side of equations.
recordp x
  Check for record values.

record x
  Normalizes a record. This removes duplicate keys and orders the record by keys (using an apparently random but well-defined order of the key values), so that normalized records are syntactically equal (==) if and only if they contain the same hash pairs. For convenience, this function can also be used directly on lists and tuples of hash pairs to convert them to a normalized record value.

# x
  The size of a record (number of entries it contains). Duplicate entries are counted. (This is in fact just the standard matrix size operation.)

member x y
  Check whether x contains the key y.

x ! y
  Retrieves the (last) value associated with the key y in x, if any, otherwise throws an out_of_bounds exception.

x !!! ys
  Slicing also works as expected, by virtue of the generic definition of slicing provided by the matrix data structure.

insert x (y=>z)
update x y z
  Associate the key y with the value z in x. If x already contains the key y then the corresponding value is updated (the last such value if x contains more than one association for y), otherwise a new member is inserted at the end of the record.

delete x y
  Delete the key y (and its associated value) from x. If x contains more than one entry for y then the last such entry is removed.

keys x
vals x
  List the keys and associated values of x. If the record contains duplicate keys, they are all listed in the order in which they are stored in the record.

Here are a few basic examples:

> let r = {x=>5, y=>12};
> r!y; r!![y,x];  // indexing and slicing
12
(12,5)
> keys r; vals r;  // keys and values of a record
{x,y}
{5,12}
> insert r (x=>99);  // update an existing entry
{x=>99,y=>12}
> insert ans (z=>77);  // add a new entry
More examples can be found in the Record Data section in the Pure Manual.

2.1.11 Primitives

This prelude module is a collection of various low-level operations, which are implemented either directly by machine instructions or by C functions provided in the runtime. In particular, this module defines the basic arithmetic and logic operations on machine integers, bigints and floating point numbers, as well as various type checking predicates and conversions between different types. Some basic pointer operations are also provided, as well as “sentries” (Pure’s flavour of object finalizers) and “references” (mutable expression pointers).

Special Constants

constant inf
constant nan

IEEE floating point infinities and NaNs. You can test for these using the infp and nanp predicates, see Predicates below.

constant NULL = pointer 0

Generic null pointer. (This is actually a built-in constant.) You can also check for null pointers with the null predicate, see Predicates.

Arithmetic

The basic arithmetic and logic operations provided by this module are summarized in the following table:
<table>
<thead>
<tr>
<th>Kind</th>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arithmetic</td>
<td>+ -</td>
<td>addition, subtraction (also unary minus)</td>
</tr>
<tr>
<td></td>
<td>* /</td>
<td>multiplication, division (inexact)</td>
</tr>
<tr>
<td></td>
<td>div mod</td>
<td>exact int/bigint division/modulus</td>
</tr>
<tr>
<td></td>
<td>^</td>
<td>exponentiation (inexact)</td>
</tr>
<tr>
<td>Comparisons</td>
<td>== ~=</td>
<td>equality, inequality</td>
</tr>
<tr>
<td></td>
<td>&lt; &gt;</td>
<td>less than, greater than</td>
</tr>
<tr>
<td></td>
<td>&lt;= &gt;=</td>
<td>less than or equal, greater than or equal</td>
</tr>
<tr>
<td>Logic</td>
<td>~</td>
<td>logical not</td>
</tr>
<tr>
<td></td>
<td>&amp;&amp;</td>
<td></td>
</tr>
<tr>
<td>Bitwise</td>
<td>not</td>
<td>bitwise not</td>
</tr>
<tr>
<td></td>
<td>and or</td>
<td>and, or</td>
</tr>
<tr>
<td></td>
<td>&lt;&lt; &gt;&gt;</td>
<td>bit shifts</td>
</tr>
</tbody>
</table>

Precedence and and associativity of the operators can be found in the operators table at the beginning of this section.

The names of some operations are at odds with C. Note, in particular, that logical negation is denoted ~ instead of ! (and, consequently, ~- denotes inequality, rather than !=), and the bitwise operations are named differently. This is necessary because Pure uses !, & and | for other purposes. Also, / always denotes inexact (double) division in Pure, whereas the integer division operators are called div and mod. (%, which is not defined by this module, also has a different meaning in Pure; it’s the exact division operator, see Rational Numbers.)

The above operations are implemented for int, bigint and, where appropriate, double operands. (Pointer arithmetic and comparisons are provided in a separate module, see Pointer Arithmetic.) The math module (see Mathematical Functions) also provides implementations of the arithmetic and comparison operators for rational, complex and complex rational numbers.

Note that the logical operations are actually implemented as special forms in order to provide for short-circuit evaluation. This needs special support from the compiler to work. The primitives module still provides definitions for these, as well as other special forms like quote and the thunking operator & so that they may be used as function values and in partial applications, but when used in this manner they lose all their special call-by-name properties; see Special Forms in the Pure Manual for details. The rules for the logical connectives are actually slightly more general than the built-in rules so that an expression of the form x&&y or x||y will always be simplified in a sensible way if at least one of the operands is a machine int; e.g., both x&&1 and 1&&x will reduce to just x if x is not a machine int.

A detailed listing of the basic arithmetic and logical operations follows below.

```plaintext
x + y
x - y
x * y
x / y
x ^ y
```

Addition, subtraction, multiplication, division and exponentiation. The latter two are inexact and will yield double results.
Unary minus. This has the same precedence as binary ‘-’ above.

\[ x \div y \quad x \mod y \]
Exact int and bigint division and modulus.

\[ x == y \quad x \neq y \]
Equality and inequality.

\[ x <= y \quad x >= y \quad x > y \quad x < y \]
Comparisons.

\[ \neg x \quad x \&\& y \quad x || y \]
Logical negation, conjunction and disjunction. These work with machine ints only and are evaluated in short-circuit mode, unless they are invoked as higher-order functions or with operands which aren’t machine ints. See the explanations above.

\[ \text{not } x \quad x \text{ and } y \quad x \text{ or } y \]
Bitwise negation, conjunction and disjunction. These work with both machine ints and bigints.

\[ x << k \quad x >> k \]
Arithmetic bit shifts. The left operand \( x \) may be a machine int or a bigint. The right operand \( k \) must be a machine int and denotes the (nonnegative) number of bits to shift.

**Note:** This operation may expand to a single machine instruction in the right circumstances, thus the condition that \( k \) be nonnegative isn’t always checked. This may lead to surprising results if you do specify a negative value for \( k \). However, in the current implementation bigint shifts do check the sign of \( k \) and handle it in the appropriate way, by turning a left shift into a corresponding right shift and vice versa.

In addition, the following arithmetic and numeric functions are provided:

\[ \text{abs } x \quad \text{sgn } x \]
Absolute value and sign of a number.

\[ \text{min } x \ y \quad \text{max } x \ y \]
Minimum and maximum of two values. This works with any kind of values which
have the ordering relations defined on them.

\[ \text{succ } x \]
\[ \text{pred } x \]
Successor (+1) and predecessor (-1) functions.

\[ \text{gcd } x \ y \]
\[ \text{lcm } x \ y \]
The greatest common divisor and least common multiple functions from the GMP library. These return a bigint if at least one of the arguments is a bigint, a machine int otherwise.

\[ \text{pow } x \ y \]
Computes exact powers of ints and bigints. The result is always a bigint. Note that \( y \) must always be nonnegative here, but see the math module (Mathematical Functions) which deals with the case \( y < 0 \) using rational numbers.

**Conversions**

These operations convert between various types of Pure values.

\[ \text{hash } x \]
Compute a 32 bit hash code of a Pure expression.

\[ \text{bool } x \]
Convert a machine integer to a normalized truth value (0 or 1).

\[ \text{int } x \]
\[ \text{bigint } x \]
\[ \text{double } x \]
Conversions between the different numeric types.

\[ \text{pointer } x \]
Convert a string, int or bigint to a pointer value. Converting a string returns a pointer to the underlying UTF8-encoded C string so that it can be passed to the appropriate C functions. Converting an integer gives a pointer with the given numeric address. This may be used to construct special pointer values such as the null pointer (pointer 0).

\[ \text{ubyte } x \]
\[ \text{ushort } x \]
\[ \text{uint } x \]
\[ \text{uint64 } x \]
\[ \text{ulong } x \]
Convert signed (8/16/32/64) bit integers to the corresponding unsigned quantities. These functions behave as if the value was “cast” to the corresponding unsigned C type, and are most useful for dealing with unsigned integers returned by external C routines. The routines always use the smallest Pure int type capable of holding the result: int for ubyte and ushort, bigint for uint, uint64 and ulong. All routines take int parameters. In the case of uint64, a bigint parameter is also permitted (which is what the C interface returns for 64 bit values). Also note that ulong reduces to either uint or uint64, depending on the size of long for the host architecture.
The following rounding functions work with all kinds of numbers:

- `floor x`
- `ceil x`
  
  Floor and ceil.
- `round x`
- `trunc x`
  
  Round or truncate to an integer.
- `frac x`

  Fractional part \( x - \text{trunc} \ x \).

Note that all these functions return double values for double arguments, so if you need an integer result then you’ll have to apply a suitable conversion, as in `int (floor x)`.

**Predicates**

A syntactic equality test is provided, as well as various type checking predicates. Note that type definitions are provided for most of the type checking predicates which don’t denote built-in types; see Prelude Types for details.

- `same x y`
- `x === y`
- `x !== y`

  Syntactic equality. In contrast to `==` and `~=` this is defined on all Pure expressions. Basically, two expressions are syntactically equal if they print out the same in the interpreter. In the special case of pointer objects and closures, which do not always have a syntactic representation in Pure, \( x \) and \( y \) must be the same object (same pointer value or function).

- `typep ty x`

  Generic type checking predicate. This checks whether \( x \) is of type \( ty \), where \( ty \) is a symbol denoting any of the built-in types (`int`, `bigint` etc.) or any type defined in a type definition. (Note that you may have to quote \( ty \) if it happens to be defined as a variable or parameterless function.)

- `intp x`
- `bigintp x`
- `doublep x`
- `stringp x`
- `pointerp x`
- `matrixp x`

  Predicates to check for the built-in types.

- `boolp x`

  Predicate to check for normalized truth values (0 and 1).

- `charp x`

  Predicate to check for single character strings.

- `numberp x`
Additional number predicates. Note some further “semantic” number predicates are defined in the math module, see Semantic Number Predicates and Types.

`exactp` x
`inexactp` x

Check whether a number is exact (i.e., doesn’t contain any double components).

`infp` x
`nanp` x

Check for inf and nan values.

`null p` x

Check for null pointers.

`applp` x
`listp` x
`rlistp` x
`tuplep` x

Predicates to check for function applications, lists, proper lists and tuples. Note that listp only checks for a toplevel list constructor, whereas rlistp also recursively checks the tails of the list; the latter may need time proportional to the list size. The applp and tuplep predicates look for an application or tuple constructor at the toplevel only, which can always be done in constant time.

`funp` x
`lambdap` x
`thunkp` x
`closurep` x

Predicates to check for various kinds of function objects (named, anonymous or thunk). closurep checks for any kind of “normal” closure (i.e., named functions and lambdas, but not thunks).

`functionp` x

Convenience function to check for “callable” functions. This includes any kind of closure with a nonzero argument count as well as partial (unsaturated) applications of these.

`symbolp` x
`varp` x

Predicates to check for any kind of symbol (this also includes operator and nonfix symbols) and for free variable symbols, respectively. Note that varp returns true for any symbol which is not an operator or nonfix symbol (i.e., for any symbol that could in principle be bound to a value, either globally or locally). This holds even if the symbol is currently bound to a function, macro or constant.
Inspection

The following operations let you peek at various internal information that the interpreter provides to Pure programs either for convenience or for metaprogramming purposes. They are complemented by the evaluation primitives discussed below, see Eval and Friends.

**ans**

Retrieve the most recently printed result of a toplevel expression evaluated in the read-eval-print loop. This is just a convenience for interactive usage. Note that the ans value will stick around until a new expression is computed. (It is possible to clear the ans value with the interactive command clear ans, however.) Example:

> 1/3;
0.333333333333333
> ans/2;
0.166666666666667

**__func__**

Returns the (lexically) innermost function at the point of the call. This can be either a global function, a local (named) function introduced in a with clause or an anonymous function (a lambda). Fails (returning just the literal symbol __func__ by default) if there is no such function (i.e., if the call is at the toplevel). Note that in contrast to the C99 variable of the same name, this really returns the function value itself in Pure; the str function can be used if you need the print name of the function. Examples:

> foo x = if x>0 then x else throw __func__;
> foo (-99);
<stdin>, line 2: unhandled exception 'foo' while evaluating 'foo (-99)'
> (\x->x+"":+str __func__) "test";
"test: #<closure 0x7f4a2411db30>"

If you want, you can add a default rule for __func__ which specifies the behaviour when __func__ gets called at the global level. E.g.:

> __func__ = throw "__func__ called at global level";
> __func__;
<stdin>, line 5: unhandled exception "__func__ called at global level" while evaluating '__func__'  

**macro __namespace__**

Returns the current namespace at the point of the call. This is implemented as a built-in macro which expands to a string. The empty string is returned in the default namespace. Example:

> namespace foo;
> foo = __namespace__;
> namespace;
> show foo::foo
foo::foo = "foo";
> foo::foo;
"foo"
macro __dir__
macro __file__

Returns the directory and absolute filename of the current script, using the canonicalized pathname of the script, as explained in *Modules and Imports*. The directory name is always terminated with a trailing slash. These macros are useful, e.g., for debugging purposes or if a script needs to locate other files relative to the script file. Like __namespace__, these are built-in macros which expand to string values.

The script name is resolved at compile time, so these macros are most useful if a script is run through the interpreter. Also note that both macros return the empty string if the code containing the call is not in a script (i.e., if it is executed directly at the interactive command line or through eval). For instance, assume that the following code is stored in the file /home/user/test.pure:

```
foo = __file__, __dir__;
bar = eval "__file__, __dir__";
```

Then running this script interactively you’ll get the following:

```
> foo;
"/home/user/test.pure","/home/user/
> bar;
"
```

macro __list__

This expands a (literal) tuple to a list, preserving embedded tuples in the same way that list values are parsed in the Pure language, cf. *Primary Expressions*. This is provided for the benefit of custom aggregate notations (usually implemented as outfix operators) which are supposed to be parsed like the built-in list and matrix brackets. Example:

```
> outfix (: :);
> def (:x:) = __list__ x;
> (: (1,2), (3,4) :);
[(1,2), (3,4)]
```

Note that this macro uses internal information from the parser not available to Pure programs. Thus there’s no way to actually define this macro in Pure, which is why it is provided as a builtin instead.

Another rather obscure point that deserves mentioning here is that the special processing of parenthesized expressions happens also if the macro is applied in prefix form. This should rarely be a problem in practice, but if it is then you can use $ to pass arguments without adding an (undesired) extra level of parentheses:

```
> ((::)) ((1,2), (3,4));
[(1,2,3,4)]
> ((::)) $ (1,2), (3,4);
[(1,2), (3,4)]
```

Note that the first expression is really equivalent to ((::)) ((1,2), (3,4))::, not ((::)) (1,2), (3,4): which can be specified in prefix form using $ as shown in the second expression. (Remember that $ is also implemented as a macro and so is substituted
away at macro expansion time in the example above.) The same trick works if for some reason you want to apply \texttt{\_\_list\_} in a direct fashion:

```haskell
> \_\_list\_ ((1,2),(3,4));
[(1,2,3,4)]
> \_\_list\_ $ (1,2),(3,4);
[(1,2),(3,4)]
```

\textbf{macro \_\_locals\_}

Built-in macro which expands to a list with the local function bindings (\texttt{with} clauses) visible at this point in the program. The return value is a list of hash pairs \texttt{x=>f} where \texttt{x} is the global symbol denoting the function (the symbol is always quoted) and \texttt{f} is the function value itself. Example:

```haskell
> \_\_locals\_ with foo x = x+1; x = a+b end;
[x=>a+b,foo=>foo]
```

The \texttt{\_\_locals\_} macro is useful for debugging purposes, as well as to implement dynamic environments. It is also used internally to implement the \texttt{reduce} macro, see \textit{Eval and Friends}. Here are some things that you should keep in mind when working with this macro:

- \texttt{\_\_locals\_} always evaluates parameterless functions and returns the resulting value instead of a closure (as can be seen in the binding \texttt{x=>a+b} in the example above). Normally this is what you want, but it can be a problem with parameterless functions involving side effects. In such a case, if you want to evaluate the function at a later time, you’ll either have to use a thunk or massage the local function so that it takes a dummy argument such as (\texttt{}).

- If the call to \texttt{\_\_locals\_} is inside a local function then that local function will itself be \textit{excluded} from the constructed environment. This is done in order to prevent infinite recursion if the calling function does not have any parameters (which is a common idiom, especially in applications of the \texttt{reduce} macro). If you really want the calling function to be in the environment, you’ll have to add it to the result of \texttt{\_\_locals\_} yourself. Using the \texttt{\_\_func\_} primitive from above, we can implement this as a macro:

```haskell
def \_\_mylocals\_ = [val (str \_\_func\_)=>\_\_func\_]\_\_locals\_;
```

You can then use \texttt{\_\_mylocals\_} instead of \texttt{\_\_locals\_} whenever you want the calling function to be included in the computed environment.

- \texttt{\_\_locals\_} will use as keys in the resulting list whatever global symbols are in scope at the point of the call. By default, i.e., if no global symbol with the same print name as the local is visible at the point of the call, a symbol in the default namespace is used, as we’ve seen above. Otherwise the result may be also be a qualified symbol if such a symbol has already been declared or defined at the point of the call. For instance:

```haskell
> namespace foo;
> public foo;
> \_\_locals\_ with foo x = x+1 end;
[foo::foo=>foo]
```
This behaviour may be a bit surprising at first sight, but is consistent with the way the interpreter performs its symbol lookup, see Symbol Lookup and Creation for details.

The following functions allow you to inspect or modify the function, type, macro, constant and variable definitions of the running program. This uses a special meta representation for rewriting rules and definitions. Please see the Macros section in the Pure manual for details. Also note that these operations are subject to some limitations, please check the remarks concerning eval and evalcmd in the following subsection for details.

- `get_fundef sym` If the given symbol is defined as a function, type or macro, return the corresponding list of rewriting rules. Otherwise return the empty list.

- `get_typedef sym` If the given symbol is defined as an interface type, return its definition; otherwise return the empty list.

- `get_macdef sym` If the given symbol is defined as a function, type or macro, return the corresponding list of rewriting rules. Otherwise return the empty list.

- `get_interface sym` If the given symbol is defined as an interface type, return its definition; otherwise return the empty list.

- `get_interface_typedef sym` If the given symbol is defined as a function, type or macro, return the corresponding list of rewriting rules. Otherwise return the empty list.

- `get_vardef sym` If the given symbol is defined as a variable or constant, return the corresponding definition as a singleton list of the form `[sym --> value]`. Otherwise return the empty list.

- `get_constdef sym` If the given symbol is defined as a variable or constant, return the corresponding definition as a singleton list of the form `[sym --> value]`. Otherwise return the empty list.

The following functions may fail in case of error, in which case lasterr is set accordingly (see Eval and Friends below).

- `add_fundef rules` Add the given rewriting rules (given in the same format as returned by the `get_fundef`, `get_typedef` and `get_macdef` functions above) to the running program.

- `add_fundef_at r rules` Same as above, but add the given rewriting rules at (i.e., before) the given rule r (which must already exist, otherwise the call fails). Note that all added rules must have the same head symbol on the left-hand side, which matches the head symbol on the left-hand side of r.
add_interface sym patterns
Add the given patterns to the interface type sym (given as a symbol). If the interface
type doesn’t exist yet, it will be created.

add_interface_at sym p patterns
Same as above, but add the given patterns at (i.e., before) the given pattern p (the given
interface type must already exist and contain the given pattern, otherwise the call fails).

add_vardef rules
add_constdef rules
Define variables and constants. Each rule must take the form sym --> value with a
symbol on the left-hand side (no pattern matching is performed by these functions).

The following functions may be used to delete individual rewriting rules, interface type
patterns or variable and constant symbols.

del_fundef rule
del_typedef rule
del_macdef rule
Delete the given rewriting rule (given in the same format as returned by the
get_fundef, get_typedef and get_macdef functions) from the running program. Re-
turns () if successful, fails otherwise.

del_interface sym pattern
Delete the given pattern from the given interface type. Returns () if successful, fails
otherwise.

del_vardef sym
del_constdef sym
Delete variables and constants, given by their (quoted) symbols. Returns () if success-
ful, or fails if the symbol isn’t defined (or defined as a different kind of symbol).

The prelude also provides some functions to retrieve various attributes of a function symbol
which determine how the operation is applied to its operands or arguments. These functions
all take a single argument, the symbol or function object to be inspected, and return an
integer value.

nargs x
Get the argument count of a function object, i.e., the number of arguments it expects. Returns 0 for thunks and saturated applications, -1 for over-saturated applications and
non-functions.

arity x
Determine the arity of an operator symbol. The returned value is 0, 1 or 2 for nullary,
unary and binary symbols, respectively, -1 for symbols without a fixity declaration or
other kinds of objects.

fixity f
Determine the fixity of an operator symbol. The fixity is encoded as an integer 10*n+m
where n is the precedence level (ranging from 0 to PREC_MAX, where PREC_MAX denotes
the precedence of primary expressions, 16777216 in the current implementation) and m
indicates the actual fixity at each level, in the order of increasing precedence (0 = infix, 1
= infixl, 2 = infixr, 3 = prefix, 4 = postfix). The fixity value of nonfix and outfix symbols, as well as symbols without a fixity declaration, is always given as $10^{\text{PREC\_MAX}}$, and the same value is also reported for non-symbol objects. Infix, prefix and postfix symbols always have a fixity value less than $10^{\text{PREC\_MAX}}$. ($\text{PREC\_MAX}$ isn’t actually defined as a constant anywhere, but you can easily do that yourself by setting $\text{PREC\_MAX}$ to the fixity value of any nonfix symbol or non-symbol value, e.g.: `const \text{PREC\_MAX} = \text{fixity} [];`)

Note that only closures (i.e., named and anonymous functions and thunks) have a defined argument count in Pure, otherwise `nargs` returns -1 indicating an unknown argument count. Partial applications of closures return the number of remaining arguments, which may be zero to indicate a saturated (but unevaluated) application, or -1 for over-saturated and constructor applications. (Note that in Pure a saturated application may also remain unevaluated because there is no definition for the given combination of arguments and thus the expression is in normal form, or because the application was quoted. If such a normal form application is then applied to some “extra” arguments it becomes over-saturated.)

The value returned by `nargs` always denotes the actual argument count of the given function, regardless of the declared arity if the function also happens to be an operator symbol. Often these will coincide (as, e.g., in the case of `+` which is a binary operator and also expects two arguments). But this is not necessarily the case, as shown in the following example of a binary operator which actually takes three arguments:

```pure
> infix 0 oops;
> (oops) x y z = x*z+y;
> arity (oops);
2
> nargs (oops);
3
> nargs (5 oops 8);
1
> map (5 oops 8) (1..5);
[13,18,23,28,33]
```

**Eval and Friends**

Pure provides some rather powerful operations to convert between Pure expressions and their string representation, and to evaluate quoted expressions (`'x`). The string conversions `str`, `val` and `eval` also provide a convenient means to serialize Pure expressions, e.g., when terms are to be transferred to/from persistent storage. (Note, however, that this has its limitations. Specifically, some objects like pointers and anonymous functions do not have a parsable string representation. Also see the Expression Serialization section for some dedicated serialization operations which provide a more compact binary serialization format.)

```pure
str x
Yields the print representation of an expression in Pure syntax, as a string.

val s
 Parses a single simple expression, specified as a string in Pure syntax, and returns
```
the result as is, without evaluating it. Note that this is much more limited than the eval operation below, as the expression must not contain any of the special constructs (conditional expressions, when, with, etc.), unless they are quoted.

eval x
Parses any expression, specified as a string in Pure syntax, and returns its value. In fact, eval can also parse and execute arbitrary Pure code. In that case it will return the last computed expression, if any. Alternatively, eval can also be invoked on a (quoted) Pure expression, which is recompiled and then evaluated. Exceptions during evaluation are reported back to the caller.

Note: The use of eval and evalcmd (as well as add_fundef, add_typedef etc. from the preceding subsection) to modify a running program breaks referential transparency and hence these functions should be used with care. Also, none of the inspection and mutation capabilities provided by these operations will work in batch-compiled programs, please check the Batch Compilation section in the Pure manual for details. Moreover, using these operations to modify or delete a function which is currently being executed results in undefined behaviour.

evalcmd x
Like eval, but allows execution of interactive commands and returns their captured output as a string. No other results are returned, so this operation is most useful for executing Pure definitions and interactive commands for their side-effects. (At this time, only the regular output of a few commands can be captured, most notably bt, clear, mem, save and show; otherwise the result string will be empty.)

lasterr
Reports errors in val, eval and evalcmd (as well as in add_fundef et al, described in the previous subsection). This string value will be nonempty iff a compilation or execution error was encountered during the most recent invocation of these functions. In that case each reported error message is terminated with a newline character.

lasterrpos
Gives more detailed error information. This returns a list of the individual error messages in lasterr, along with the position of each error (if available). Each list item is either just a string (the error message, with any trailing newline stripped off) if no error position is available, or a tuple of the form msg, file, l1, c1, l2, c2 where msg is the error message, file the name of the file containing the error (which will usually be "<stdin>" indicating that the error is in the source string, but may also be a proper filename of a module imported in the evaluated code), l1, c1 denotes the beginning of the range with the erroneous construct (given as line and column indices) and l2, c2 its end (or rather the character position following it). For convenience, both line and column indices are zero-based, in order to facilitate extraction of the text from the actual source string.

Note: The indicated error positions are only approximate, and may in many cases span an entire syntactic construct (such as a subexpression or even an entire function

2.1.11 Primitives
definition) containing the error. Also, the end of the range may sometimes point one
token past the actual end of the construct. (These limitations are due to technical re-
strictions in the parser; don’t expect them to go away anytime soon.)

Examples:

```plaintext
> str (1/3);
"0.333333333333333"
> val "1/3";
1/3
> eval "1/3";
0.333333333333333
> eval ('(1/3));
0.333333333333333
> evalcmd "show evalcmd";
"extern expr* evalcmd(expr*);\n"
> eval "1/3";
eval "1/3"
> lasterr;
"<stdin>, line 1: syntax error, unexpected ')', expecting '=' or '|'\n"
> lasterrpos;
[("<stdin>, line 1: syntax error, unexpected ')', expecting '=' or '|'",
"stdin">",0,3,0,4)]
```

In addition to str, the prelude also provides the following function for pretty-printing the
internal representation used to denote quoted specials. This is commonly used in conjunc-
tion with the __show__ function, please see the Macros section in the Pure manual for details.

```plaintext
__str__ x
Pretty-prints special expressions.
```

Example:

```plaintext
> __str__ ('__lambda__ [x __type__ int] (x+1));
"||x::int -> x+1"
```

The evalcmd function is commonly used to invoke the show and clear commands for
metaprogramming purposes. The prelude provides the following two convenience func-
tions to make this easy:

```plaintext
globsym pat level
This uses evalcmd with the show command to list all defined symbols matching the
given glob pattern. A definition level may be specified to restrict the context in which
the symbol is defined; a level of 0 indicates that all symbols are eligible (see the de-
scription of the show command in the Pure manual for details). The result is the list of
all matching (quoted) symbols.
```

```plaintext
clearsym sym level
This uses evalcmd with the clear command to delete the definition of the given symbol
at the given definition level. No glob patterns are permitted here. The sym argument
may either be a string or a literal (quoted) symbol.
```
Example:

```plaintext
> let x,y = 77,99;
> let syms = globsym "[a-z]" 0; syms;
[x,y]
> map eval syms;
[77,99]
> do (flip clearsym 0) syms;
()
> globsym "[a-z]" 0;
[]
> x,y;
```

x,y

The following functions are useful for doing symbolic expression simplification.

**macro reduce x**

Reevaluates an expression in a local environment. This dynamically rebinds function symbols in the given expression to whatever local function definitions are in effect at the point of the `reduce` call. Note that `reduce` is actually implemented as a macro which expands to the `reduce_with` primitive (see below), using the `__locals__` builtin to enumerate the bindings which are in effect at the call site.

**reduce_with env x**

Like `reduce` above, but takes a list of replacements (given as hash pairs `u=>v`) as the first argument. The `reduce` macro expands to `reduce_with __locals__`.

The `reduce` macro provides a restricted form of dynamic binding which is useful to implement local rewriting rules. It is invoked without parameters and expands to the curried call `reduce_with __locals__` of the `reduce_with` primitive, which takes one additional argument, the expression to be rewritten. The following example shows how to expand or factorize an expression using local rules for the laws of distributivity:

```plaintext
expand = reduce with
  (a+b)*c = a*c+b*c;
  a*(b+c) = a*b+a*c;
end;

factor = reduce with
  a*c+b*c = (a+b)*c;
  a*b+a*c = a*(b+c);
end;

expand ((a+b)*2); // yields a*2+b*2
factor (a*2+b*2); // yields (a+b)*2
```

Note that instances of locally bound functions are substituted back in the computed result, thus the instances of `*` and `+` in the results `a*2+b*2` and `(a+b)*2` shown above denote the corresponding globals, not the local incarnations of `*` and `+` defined in `expand` and `factor`, respectively.

`reduce` also adjusts to quoted arguments. In this case, the local rules are applied as usual,
but back-substituted globals are not evaluated in the result:

```plaintext
> expand ((a+1)*2);
a=2+2
> expand ('((a+1)*2));
a=2+1=2
```

Note that `reduce` only takes into account local function bindings from `with` clauses, local variable bindings do not affect its operation in any way:

```plaintext
> let y = [x,x^2,x^3];
> reduce y when x = u+v end;
[x,x^2,x^3]
```

However, in such cases you can perform the desired substitution by turning the `when` into a `with` clause:

```plaintext
> reduce y with x = u+v end;
[u+v,(u+v)^2,(u+v)^3]
```

Or you can just invoke the underlying `reduce_with` builtin directly, with the desired substitutions given as hash pairs in the first argument:

```plaintext
> reduce_with [x=>u+v] y;
[u+v,(u+v)^2,(u+v)^3]
```

It is always a good idea to confine calls to `reduce` to global functions if possible, since this gives you better control over which local functions are in scope at the point of the call. Otherwise it might be necessary to call `__locals__` manually and filter the resulting list before submitting it to the `reduce_with` function.

### Expression Serialization

Like `str` and `eval`, the following `blob` and `val` operations can be used to safely transfer expression data to/from persistent storage and between different processes (using, e.g., POSIX shared memory, pipes or sockets). However, `blob` and `val` use a binary format which is usually much more compact and gets processed much faster than the string representations used by `str` and `eval`. Also, `val` offers some additional protection against transmission errors through a crc check. (The advantage of the string representation, however, is that it’s readable plain text in Pure syntax.)

- **blob**
  
  Stores the contents of the given expression as a binary object. The return value is a cooked pointer which frees itself when garbage-collected.

- **val**
  
  Reconstructs a serialized expression from the result of a previous invocation of the `blob` function.

- **blobp**
  
  Checks for a valid `blob` object. (Note that `val` may fail even if `blobp` returns true, because for performance reasons `blobp` only does a quick plausibility check on the
header information of the blob, whereas val also performs a crc check and verifies data integrity.)

```plaintext
# p
blob_size p
blob_crc p
```

Determines the size (in bytes) and crc checksum of a blob, respectively. blob_size always returns a bigint, blob_crc a machine int (use uint on the latter to get a proper unsigned 32 bit value). For convenience, #p is defined as an alias for blob_size p on blob pointers.

Example:

```plaintext
> let b = blob ("Hello, world!", 1/3, 4711, NULL);
b; #b; uint $ blob_crc b;
#<pointer 0x141dca0>
148L
3249898239L
> val b;
{"Hello, world!", 0.333333333333333, 4711, #<pointer 0x0>}
```

Please note that the current implementation has some limitations:

- Just as with str and eval, runtime data (local closures and pointers other than the NULL pointer) can’t be serialized, causing blob to fail. However, it is possible to transfer a global function, provided that the function exists (and is the same) in both the sending and the receiving process. (This condition can’t be verified by val and thus is at the programmer’s responsibility.)

- Sharing of subexpressions will in general be preserved, but sharing of list and tuple tails will be lost (unless the entire list or tuple is shared).

- The val function may fail to reconstruct the serialized expression even for valid blobs, if there is a conflict in symbol fixities between the symbol tables of the sending and the receiving process. To avoid this, make sure that symbol declarations in the sending and the receiving script match up.

Other Special Primitives

exit status
Terminate the program with the given status code.

throw x
Throw an exception, cf. Exception Handling.

__break__
__trace__
Trigger the debugger from a Pure program, cf. Debugging. Note that these routines only have an effect if the interpreter is run in debugging mode, otherwise they are no-ops. The debugger will be invoked at the next opportunity (usually when a function is called or a reduction is completed).
force x

Force a thunk (x&) cf. Special Forms. This usually happens automagically when the value of a thunk is needed.

**Pointer Operations**

The prelude provides a few basic operations on pointers which make it easy to interface to external C functions. For more advanced uses, the library also includes the pointers module which can be imported explicitly if needed, see Pointer Arithmetic below.

`addr` symbol

Get the address of a C symbol (given as a string) at runtime. The library containing the symbol must already be loaded. Note that this can in fact be any kind of externally visible C symbol, so it’s also possible to get the addresses of global variables. The result is returned as a pointer. The function fails if the symbol was not found.

`calloc` nmembers size

`malloc` size

`realloc` ptr size

`free` ptr

Interface to malloc, free and friends. These let you allocate dynamic buffers (represented as Pure pointer values) for various purposes.

The following functions perform direct memory accesses through pointers. Their primary use is to interface to certain C library functions which take or return data through pointers. It goes without saying that these operations should be used with utmost care. No checking is done on the pointer types, so it is the programmer’s responsibility to ensure that the pointers actually refer to the corresponding type of data.

`get_byte` ptr

`get_short` ptr

`get_int` ptr

`get_int64` ptr

`get_long` ptr

`get_float` ptr

`get_double` ptr

`get_string` ptr

`get_pointer` ptr

Return the integer, floating point, string or generic pointer value at the memory location indicated by ptr.

`put_byte` ptr x

`put_short` ptr x

`put_int` ptr x

`put_int64` ptr x

`put_long` ptr x

`put_float` ptr x

`put_double` ptr x

`put_string` ptr x
put_pointer \( \text{ptr} \ x \)
Change the integer, floating point, string or generic pointer value at the memory location indicated by \( \text{ptr} \) to the given value \( x \).

Sentries

Sentries are Pure’s flavour of object finalizers. A sentry is simply an object (usually a function) which gets applied to the target expression when it is garbage-collected. This is useful to perform automatic cleanup actions on objects with internal state, such as files. Pure’s sentries are much more useful than finalizers in other garbage-collected languages, since it is guaranteed that they are called as soon as an object “goes out of scope”, i.e., becomes inaccessible.

sentry \( f \ x \)
Places a sentry \( f \) at an expression \( x \) and returns the modified expression.

clear_sentry \( x \)
Removes the sentry from an expression \( x \).

get_sentry \( x \)
Returns the sentry of an expression \( x \) (if any, fails otherwise).

As of Pure 0.45, sentries can be placed on any Pure expression. The sentry itself can also be any type of object (but usually it’s a function). Example:

```pured
> using system;
> sentry (\_\_\_\_->puts "I’m done for!") (1..3);
[1,2,3]
> clear ans
I’m done for!
```

Note that setting a finalizer on a global symbol won’t usually be of much use since such values are cached by the interpreter. (However, the sentry will be invoked if the symbol gets recompiled because its definition has changed. This may be useful for some purposes.)

In Pure parlance, we call an expression cooked if a sentry has been attached to it. The following predicate can be used to check for this condition. Also, there is a convenience function to create cooked pointers which take care of freeing themselves when they are no longer needed.

cookedp \( x \)
Check whether a given object has a sentry set on it.

cooked \( \text{ptr} \)
Create a pointer which disposes itself after use. This is just a shorthand for sentry free. The given pointer \( \text{ptr} \) must be malloced to make this work.

Example:

```pured
> using system;
> let p = cooked (malloc 1024);
> cookedp p;
1
```

2.1.11 Primitives 293
Besides their use as finalizers, sentries can also be handy in other circumstances, when you need to associate an expression with another, “invisible” value. In this case the sentry is usually some kind of data structure instead of a function to be executed at finalization time. For instance, here’s how we can employ sentries to implement hashing of function values:

```
using dict;
hashed f x = case get_sentry f of
    h::hdict = h!x if member h x;
    _ = y when y = f x; sentry (update h x y) f
    when h = case get_sentry f of
        h::hdict = h; _ = emptyhdict
        end;
    end;
    end;

E.g., consider the naive recursive definition of the Fibonacci function:

fib n::int = if n<=1 then 1 else fib (n-1)+fib (n-2);

A hashed version of the Fibonacci function can be defined as follows:

let hfib = hashed f with
    f n::int = if n<=1 then 1 else hfib (n-1)+hfib (n-2)
end;

This turns the naive definition of the Fibonacci function (which has exponential time complexity) into a linear time operation:

> stats
> fib 35;
14930352
4.53s
> hfib 35;
14930352
0.25s

Finally, note that there can be only one sentry per expression but, building on the operations provided here, it’s easy to design a scheme where sentries are chained. For instance:

chain_sentry f x = sentry (h (get_sentry x)) x with
    h g x = g x $$ f x;
end;

This invokes the original sentry before the chained one:

> using system;
> f _ = puts "sentry#1"; g _ = puts "sentry#2";
> let p = chain_sentry g $ sentry f $ malloc 10;
You can chain any number of sentries that way. This scheme should work in most cases in which sentries are used just as finalizers. However, there are other uses, like the “hashed function” example above, where you’d like the original sentry to stay intact. This can be achieved by placing the new sentry as a sentry on the original sentry rather than the expression itself:

```pure
attach_sentry f x = sentry (sentry f (get_sentry x)) x;
```

This requires that the sentry will actually be garbage-collected when its hosting expression gets freed, so it will not work if the original sentry is a global:

```pure
> let p = attach_sentry g $ sentry f $ malloc 10;
> clear p
sentry#1
```

However, the attached sentry will work ok if you can ensure that the original sentry is a (partial or constructor) application. E.g.:

```pure
> let p = attach_sentry g $ sentry (f$) $ malloc 10;
> clear p
sentry#1
sentry#2
```

### Tagged Pointers

As of Pure 0.45, the C interface now fully checks pointer parameter types at runtime (see the C Types section in the Pure Manual for details). To these ends, pointer values are internally tagged to keep track of the pointer types. The operations described in this section give you access to these tags in Pure programs. At the lowest level, a pointer tag is simply a machine int associated with a pointer value. The default tag is 0, which denotes a generic pointer value, i.e., `void*` in C. The following operations are provided to create such tags, and set, get or verify the tag of a pointer value.

- **ptrtag t x**
  
  Places an integer tag t at an expression x and returns the modified expression. x must be a pointer value.

- **get_ptrtag x**
  
  Retrieves the tag associated with x.

- **check_ptrtag t x**
  
  Compares the tag associated with x against t and returns true iff the tags match. If x is a pointer value, this is equivalent to `get_ptrtag x==t || null x && get_ptrtag x==0`.

- **make_ptrtag**
  
  Returns a new, unique tag each time it is invoked.
Examples:

```plaintext
> let p = malloc 10;
> get_ptrtag p; // zero by default
0
> let t = make_ptrtag; t;
12
> ptrtag t p;
#<pointer 0xc42da0>
> get_ptrtag p;
12
> check_ptrtag t p;
1
> check_ptrtag 0 p;
0
```

Note that in the case of a non-NULL pointer, `check_ptrtag` just tests the tags for equality. On the other hand, a generic NULL pointer, like in C, is considered compatible with all pointer types:

```plaintext
> let t1 = make_ptrtag; t1;
13
> check_ptrtag t1 p;
0
> check_ptrtag t1 NULL;
1
> get_ptrtag NULL;
0
```

The operations above are provided so that you can design your own, more elaborate type systems for pointer values if the need arises. However, you’ll rarely have to deal with pointer tags at this level yourself. For most applications, it’s enough to inspect the type of a Pure pointer and maybe modify it by “casting” it to a new target type. The following high-level operations provide these capabilities.

**pointer_tag**

```plaintext
pointer_tag ty
```

Returns the pointer tag for the given type `ty`, denoted as a string, or the given pointer value `x`. In the former case, the type should be specified in the C-like syntax used in `extern` declarations; a new tag will be created using `make_ptrtag` if needed. In the latter case, `pointer_tag` simply acts as a frontend for `get_ptrtag` above.

**pointer_type**

```plaintext
pointer_type tag
```

Returns the type name associated with the given int value `tag` or pointer value `x`. Please note that this may be `NULL` in the case of an “anonymous” tag, which may have been created with `make_ptrtag` above, or if the tag is simply unknown because it hasn’t been created yet.

**pointer_cast**

```plaintext
pointer_cast tag x
```

Casts `x` (which must be a pointer value) to the given pointer type, which may be spec-
ified either as a tag or a string denoting the type name. This returns a new pointer value with the appropriate type tag on it (the tag on the original pointer value $x$ isn’t affected by this operation).

Example:

```plaintext
> let p = malloc 10;
> let q = pointer_cast "char*" p;
> map pointer_type [p,q];
["void*","char*"]
> map pointer_tag [p,q];
[0,1]
> map pointer_type (0..make_ptrtag-1);
["void*","char*","void**","char***","short*","short**","int*","int**",
"float*","float**","double*","double**"]
```

(The last command shows a quick and dirty way to retrieve the currently defined type tags in the interpreter. This won’t work in batch-compiled scripts, however, since in this case the range of type tags is in general non-contiguous.)

If you have to do many casts to a given type, you can avoid the overhead of repeatedly looking up the type name by assigning the tag to a variable, which can then be passed to `pointer_cast` instead:

```plaintext
> let ty = pointer_tag "long*";
> pointer_cast ty p, pointer_cast ty q;
```

Note that you have to be careful when casting a cooked pointer, because `pointer_cast` may have to create a copy of the original pointer value in order not to clobber the original type tag. The sentry will then still be with the original cooked pointer value, thus you have to ensure that this value survives its type-cast duplicate. It’s usually best to apply the cast right at the spot where the pointer gets passed to an external function, e.g.:

```plaintext
> extern char *gets(char*);
> let p = cooked $ malloc 1000;
> gets (pointer_cast "char*" p);
```

Such usage is always safe. If this approach isn’t possible, you might want to use the lowlevel `ptrtag` operation instead. (This will clobber the type tag of the pointer, but you can always change it back afterwards.)

**Expression References**

Expression references provide a kind of mutable data cells which can hold any Pure expression. If you need these, then you’re doomed. ;-) However, they can be useful as a last resort when you need to keep track of some local state or interface to the messy imperative world. Pure’s references are actually implemented as expression pointers so that you can readily pass them as pointers to a C function which expects a `pure_expr**` parameter. This may even be useful at times.

**type ref**

The type of expression references. This is a subtype of the `pointer` type.

**2.111 Primitives**
Create a reference pointing to \( x \) initially.

Set a new value \( x \), and return that value.

Retrieve the current value \( r \) points to.

Purge the referenced object and turn the reference into a dangling pointer. (This is used as a sentry on reference objects and shouldn’t normally be called directly.)

Predicate to check for reference values.

Note that manually changing or removing the `unref` sentry of a reference turns the reference into just a normal pointer object and renders it unusable as a reference. Doing this will also leak memory, so don’t!

There is another pitfall with expression references, namely that they can be used to create cyclic chains which currently can’t be reclaimed by Pure’s reference-counting garbage collector. For instance:

```plaintext
> using system;
> done r = printf "done %s\n" (str r);
> let x = ref ();
> let y = ref (sentry done 2,x);
> put x (sentry done 1,y);
1,#<pointer 0x3036400>
```

At this point \( x \) points to \( y \) and vice versa. If you now purge the \( x \) and \( y \) variables then Pure won’t be able to reclaim the cycle, resulting in a memory leak (you can verify this by noting that the sentries are not being called). To prevent this, you’ll have to break the cycle first:

```plaintext
> put y 3;
> done 2
3
> clear x y
done 1
```

Note that, in a way, sentries work similar to expression references and thus the same caveats apply there. Having a limited amount of cyclic references won’t do any harm. But if they can grow indefinitely then they may cause problems with long-running programs due to memory leakage, so it’s a good idea to avoid such cycles if possible.

**Pointer Arithmetic**

The pointers.pure module provides the usual C-style pointer arithmetic and comparisons of pointer values. This module normally is not included in the prelude, so to use these operations, you have to add the following import declaration to your program:
using pointers;

The module overloads the comparison and some of the arithmetic operators (cf. Arithmetic) so that they can be used to compare pointers and to perform C-style pointer arithmetic. To these ends, some conversions between pointers and numeric types are also provided.

\[
\text{int } p
\]

\[
\text{bigint } p
\]

Convert a pointer to an int or bigint, giving its numeric address value, which usually denotes a byte offset relative to the beginning of the memory of the executing process. This value can then be used in arithmetic operations and converted back to a pointer using the \texttt{pointer} function from the prelude. (Note that to make this work on 64 bit systems, you’ll have to convert the pointer values to bigints.)

\[
p + n
\]

\[
p - n
\]

\[
p - q
\]

Pointer arithmetic. \(p+n\) and \(p-n\) offsets a pointer \(p\) by the given integer \(n\) denoting the amount of bytes. In addition, \(p-q\) returns the byte offset between two pointers \(p\) and \(q\). Note that, in contrast to C pointer arithmetic which also takes into account the base type of the pointer, the Pure operations always use byte offsets, no matter what type of pointer (as given by the pointer tag) is passed to these operations.

\[
p == q
\]

\[
p \neq q
\]

Pointer equality and inequality. This is exactly the same as syntactic equality on pointers.

\[
p <= q
\]

\[
p >= q
\]

\[
p > q
\]

\[
p < q
\]

Pointer comparisons. One pointer \(p\) is considered to be “less” than another pointer \(q\) if it represents a “lower” address in memory, i.e., if the byte offset \(p-q\) is negative.

2.2 Mathematical Functions

The math.pure module provides Pure’s basic math routines. It also defines complex and rational numbers.

2.2.1 Imports

To use the operations of this module, add the following import declaration to your program:

using math;

2.2.2 Basic Math Functions

The module defines the following real-valued constants:
**constant e = 2.71828...**  
Euler’s number.

**constant pi = 3.1415...**  
Ludolph’s number.

It also provides a reasonably comprehensive (pseudo) random number generator which uses the **Mersenne twister** to avoid bad generators present in some C libraries.

Please note that as of Pure 0.41, the runtime library includes a newer release of the Mersenne twister which fixes issues with some kinds of seed values, and will yield different values for given seeds. Also, the `random31` and `random53` functions have been added as a convenience to compute unsigned 31 bit integers and 53 bit double values, and the `srandom` function now also accepts an int matrix as seed value.

**random**  
Return 32 bit pseudo random ints in the range `-0x80000000..0x7fffffff`.

**random31**  
Return 31 bit pseudo random ints in the range `0..0x7fffffff`.

**random53**  
Return pseudo random doubles in the range `{0, 1}` with 53 bits resolution.

**srandom seed**  
Sets the seed of the generator to the given 32 bit integer. You can also specify longer seeds using a nonempty row vector, e.g.: `srandom {0x123, 0x234, 0x345, 0x456}`.

The following functions work with both double and int/bigint arguments. The result is always a double. For further explanations please see the descriptions of the corresponding functions from the C math library.

**sqrt x**  
The square root function.

**exp x**  
**ln x**  
**log x**  
Exponential function, natural and decadic logarithms.

**sin x**  
**cos x**  
**tan x**  
Trigonometric functions.

**asin x**  
**acos x**  
**atan x**  
Inverse trigonometric functions.

**atan2 y x**  
Computes the arcus tangent of `y/x`, using the signs of the two arguments to determine the quadrant of the result.
Hyperbolic trigonometric functions.

Inverse hyperbolic trigonometric functions.

2.2.3 Complex Numbers

Complex number constructors.

Constant \(i = 0+1\)

Imaginary unit.

We provide both rectangular \((x:+:y)\) and polar \((r<:t)\) representations, where \((x,y)\) are the Cartesian coordinates and \((r,t)\) the radius (absolute value) and angle (in radians) of a complex number, respectively. The \(+:\) and \(<:\) constructors (declared in the prelude) bind weaker than all other arithmetic operators and are non-associative.

The polar representation \(r<:t\) is normalized so that \(r\) is always nonnegative and \(t\) falls in the range \(-\pi<t<\pi\).

The constant \(i\) is provided to denote the imaginary unit \(0+:1\).

The arithmetic operations \(+, *, \) etc. and the equality relations \(==\) and \(~~=\) work as expected, and the square root, exponential, logarithms, trigonometric and hyperbolic trigonometric functions (see Basic Math Functions) are extended to complex numbers accordingly. These do not rely on complex number support in the C library, but should still conform to IEEE 754 and POSIX, provided that the C library provides a standards-compliant implementation of the basic math functions.

The following operations all work with both the rectangular and the polar representation, promoting real (double, int/bigint) inputs to complex where appropriate. When the result of an operation is again a complex number, it generally uses the same representation as the input (except for explicit conversions). Mixed rect/polar and polar/rect arithmetic always returns a rect result, and mixed complex/real and real/complex arithmetic yields a rect or polar result, depending on what the complex input was.

Convert any kind of number to a complex value.

Convert between polar and rectangular representations.

Create complex values on the unit circle. Note: To quickly compute \(\exp (x+:y)\) in
polar form, use \( \exp x <: y \).

### Abs

#### Abs

- \( \text{abs} z \)

Modulus (absolute value) and argument (angle, a.k.a. phase). Note that you can also find both of these in one go by converting to polar form.

#### Arg

- \( \arg z \)

Real and imaginary part.

### Conj

#### Conj

Complex conjugate.

Examples:

```
> using math;
> let z = 2^(1/1); z;
0.769238901363972+:-0.638961276313635
> let z = ln z/ln 2; z;
0.0+:.-1.0
> abs z, arg z;
1.0,-1.5707963267949
> polar z;
1.0<:-1.5707963267949
```

Please note that, as the \(+:\) and \(<:\) constructors bind weaker than the other arithmetic operators, complex numbers must be parenthesized accordingly, e.g.:

```
> (1+:2)*(3+:4);
-5+:10
```

### 2.2.4 Rational Numbers

#### X % y

Exact division operator and rational number constructor.

Pure’s rational numbers are constructed with the exact division operator % (declared in the prelude) which has the same precedence and fixity as the other division operators.

The % operator returns a rational or complex rational for any combination of integer, rational and complex integer/rational arguments, provided that the denominator is nonzero (otherwise it behaves like \( x \div 0 \), which will raise an exception). Machine int operands are always promoted to bigints, thus normalized rationals always take the form \( x%y \) where both the numerator \( x \) and the denominator \( y \) are bigints. For other numeric operands % works just like /. Rational results are normalized so that the sign is always in the numerator and numerator and denominator are relatively prime. In particular, a rational zero is always represented as 0L%1L.

The usual arithmetic operations and equality/order relations are extended accordingly, as well as the basic math functions and the rounding functions, and will return exact (rational
or complex rational) results where appropriate. Rational operations are implemented using the GMP bigint functions where possible, and thus are reasonably fast.

In addition, the module also provides following operations:

**rational** \( x \)

Converts a real or complex value \( x \) to a rational or complex rational. Note that the conversion from double values doesn’t do any rounding, so it is guaranteed that converting the resulting rational back to a double reconstructs the original value.

Conversely, the **int**, **bigint**, **double**, **complex**, **rect**, **polar** and **cis** conversion functions are overloaded so that they convert a rational to one of the other number types.

**num** \( x \)

**den** \( x \)

Numerator and denominator of a rational \( x \).

Examples:

```plaintext
> using math;
> 5%7 + 2%3;
29L%21L
> 3%8 - 1%3;
1L%24L
> pow (11%10) 3;
1331L%1000L
> let x = pow 3 (-3); x;
1L%27L
> num x, den x;
1L,27L
> rational (3/4);
3L%4L
```

Note that doubles can’t represent most rationals exactly, so conversion from double to rational will yield funny results in many cases (which are still accurate up to rounding errors). For instance:

```plaintext
> let x = rational (1/17); x;
423868202231055L%72057594037927936L
> num x/den x;
0.0588235294117647
> double (1%17);
0.0588235294117647
```

### 2.2.5 Semantic Number Predicates and Types

In difference to the syntactic predicates in *Primitives*, these check whether the given value can be represented as an object of the given target type (up to rounding errors). Note that if \( x \) is of syntactic type \( X \), then it is also of semantic type \( X \). Moreover, \( \text{intvalp} \ x \Rightarrow \text{bigintvalp} \ x \Rightarrow \text{ratvalp} \ x \Rightarrow \text{realvalp} \ x \Rightarrow \text{compvalp} \ x \Leftrightarrow \text{numberp} \ x. \)

**compvalp** \( x \)

Check for complex values (this is the same as **numberp**).
realvalp x
    Check for real values (im x==0).
ratvalp x
    Check for rational values (same as realvalp, except that IEEE 754 infinities and NaNs are excluded).
bigintvalp x
    Check for “big” integer values which can be represented as a bigint.
intvalp x
    Check for “small” integer values which can be represented as a machine int.

type compval
type realval
type ratval
type bigintval
type intval
    Convenience types for the above predicates. These can be used as type tags on the left-hand side of an equation to match numeric values for which the corresponding predicate yields true.

2.3 Enumerated Types

Enumerated types, or enumerations for short, are algebraic types consisting only of nullary constructor symbols. The operations of this module equip such types with the necessary function definitions so that the members of the type can be employed in arithmetic operations, comparisons, etc. in the same way as the predefined enumerated types such as integers and characters. This also includes support for arithmetic sequences.

Please note that this module is not included in the prelude by default, so you have to use the following import declaration to get access to its operations:

class using enum;

Also note that the enum and defenum functions use meta-programming to modify the running program, which only works when running in the interpreter. Thus, if a script using these functions is to be compiled to a native executable, you need to make sure that calls to enum and defenum are invoked at compile time. The const keyword does this for you, e.g.:

const enum day;

This isn’t necessary if the script runs in the interpreter, but it won’t hurt there either, so to be on the safe side, it is recommended to just always use const with these operations.

The following operations are provided:

def enum sym
    The given symbol must denote an algebraic type consisting only of nonfix symbols. enum adds the necessary rules for making members of the type work with enumerated type operations such as ord, succ, pred, comparisons, basic arithmetic and arithmetic
sequences. It also defines `sym` as an ordinary function, called the **enumeration function** of the type, which maps ordinal numbers to the corresponding members of the type (sym 0 yields the first member of the type, sym 1 the second, etc.). The members of the type are in the same order as given in the definition of the type.

```plaintext
defenum sym [symbols,...]
    A convenience function which declares a type sym with the given elements and invokes `enum` on it to make it enumerable in one go.
```

```plaintext
defenum sym [symbols,...]
```

```plaintext
enumof sym
    Given a member of an enumerated type as defined with `enum`, this returns the enumeration function of the type. Rules for this function are generated automatically by `enum`.
```

```plaintext
type enum
    The type of all enumerated type members. This is actually implemented as an interface type. It matches members of all enumerated types constructed with `enum`.
```

```plaintext
defenum sym [symbols,...]
```

```plaintext
enumof sym
```

```plaintext
pred enum x
    Predicate to check for enumerated type members.
```

For instance, consider:

```plaintext
nonfix sun mon tue wed thu fri sat;
type day sun | day mon | day tue | day wed | day thu | day fri | day sat;
```

Once the type is defined, we can turn it into an enumeration simply as follows:

```plaintext
const enum day;
```

There’s also a convenience function `defenum` which defines the type and makes it enumerable in one go:

```plaintext
const defenum day [sun,mon,tue,wed,thu,fri,sat];
```

In particular, this sets up the functions `day` and `ord` so that you can convert between members of the `day` type and the corresponding ordinals:

```plaintext
> ord sun;
0
> day (ans+3);
wed
```

You can also retrieve the type of an enumerated type member (or rather its enumeration function) with `enumof`:

```plaintext
> enumof sun;
day
> ans 5;
fri
```

Basic arithmetic, comparisons and arithmetic sequences also work as usual, provided that the involved members are all from the same enumeration:
Note that given one member of the enumeration, you can use \texttt{enumof} to quickly enumerate all members of the type starting at the given member. Here’s a little helper function which does this:

\begin{verbatim}
enumerate x::enum = iterwhile (typep ty) succ x when ty = enumof x end;
\end{verbatim}

For instance:

\begin{verbatim}
> enumerate sun;
[sun,mon,tue,wed,thu,fri,sat]
\end{verbatim}

Also note that \texttt{enum} silently skips elements which are already enumerated type members (no matter whether of the same or another type). Thus if you later add more elements to the \texttt{day} type, you can just call \texttt{enum} again to update the enumeration accordingly:

\begin{verbatim}
> succ sat;
sat+1
> type day doomsday;
> enum day;
()
> succ sat;
doomsday
\end{verbatim}

### 2.4 Container Types

The standard library provides a variety of efficient container data structures for different purposes. These are all purely functional, i.e., immutable data structures implemented using different flavours of binary trees. This means that instead of modifying a data structure in-place, operations like insertion and deletion return a new instance of the container, keeping the previous instance intact. Nevertheless, all operations are performed efficiently, in logarithmic time where possible.

The container types are all implemented as abstract data structures, so client modules shouldn’t rely on the internal representation. Each type provides a corresponding type tag.
(cf. *Type Tags* in the Pure Manual), as given in the description of each type, which can be used to match values of the type, e.g.:

\[
\text{shift a::array} = \text{rmfirst a};
\]

All container types implement the equality predicates `==` and `~=` by recursively comparing their members. In addition, the dictionary, set and bag data structures also provide the other comparison predicates (`<`, `<=` etc.) which check whether one dictionary, set or bag is contained in another.

### 2.4.1 Arrays

The array.pure module implements an efficient functional array data structure which allows to access and update individual array members, as well as to add and remove elements at the beginning and end of an array. All these operations are carried out in logarithmic time.

#### type array

The array data type.

#### Imports

To use the operations of this module, add the following import declaration to your program:

```plaintext
using array;
```

#### Operations

- **emptyarray**
  - return the empty array

- **array xs**
  - create an array from a list `xs`

- **array2 xs**
  - create a two-dimensional array from a list of lists

- **mkarray x n**
  - create an array consisting of `n x`'s

- **mkarray2 x (n,m)**
  - create a two-dimensional array of `n*m x`'s

- **arrayp x**
  - check whether `x` is an array

- **# a**
  - size of `a`

- **a ! i**
  - return the `i`th member of `a`

- **a ! (i,j)**
  - two-dimensional subscript
null a
    test whether a is the empty array

members a
list a
    list of values stored in a

members2 a
list2 a
    list of members in a two-dimensional array

first a
last a
    first and last member of a

rmfirst a
rmlast a
    remove first and last member from a

insert a x
    insert x at the beginning of a

append a x
    append x to the end of a

update a i x
    replace the i-th member of a by x

update2 a (i,j) x
    update two-dimensional array

Examples
Import the module:
> using array;

A one-dimensional array:
> let a::array = array (0.0:0.1..1.0);
> #a; members a;
  11
  [0.0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1.0]

Indexing an array works in the usual way, using Pure’s ! operator. By virtue of the prelude, slicing an array with !! also works as expected:
> a!5;
  0.5
> a!!(3..7);
  [0.3,0.4,0.5,0.6,0.7]

Updating a member of an array produces a new array:
> let b::array = update a 1 2.0;
> members b;
[0.0,2.0,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1.0]

Two-dimensional arrays can be created with array2 from a list of lists:

> let a2::array = array2 [[i,x | x = [u,v,w]] | i = 1..2];
> members2 a2;
[[[1,u),(1,v),(1,w)],[[2,u),(2,v),(2,w)]]
> a2!(1,2);
2,w
> a2!![[0,1),(1,2)];
[(1,v),(2,w)]
> a2!!(0..1,1..2);
[[[1,v),(1,w)],[[2,v),(2,w)]]

Here’s how to convert an array to a Pure matrix:

> matrix $ members a;
{0.0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1.0}
> matrix $ members2 a2;
{[[1,u),(1,v),(1,w)],[[2,u),(2,v),(2,w)]]

Converting back from a matrix to an array:

> let b2::array = array2 $ list2 {{1,u),(1,v),(1,w) ; (2,u),(2,v),(2,w)};
> members2 b2;
[[[1,u),(1,v),(1,w)],[[2,u),(2,v),(2,w)]]

2.4.2 Heaps

Heaps are a kind of priority queue data structure which allows quick (constant time) access to the smallest member, and to remove the smallest member and insert new elements in logarithmic time. Our implementation does not allow quick update of arbitrary heap members; if such functionality is required, bags can be used instead (see Sets and Bags).

Heap members must be ordered by the \( \leq \) predicate. Multiple instances of the same element may be stored in a heap; however, the order in which equal elements are retrieved is not specified.

**type heap**

The heap data type.

**Imports**

To use the operations of this module, add the following import declaration to your program:

`using heap;`
Operations

\textbf{emptyheap} \\
\hspace{1em} return the empty heap

\textbf{heap} \(xs\) \\
\hspace{1em} create a heap from a list \(xs\)

\textbf{heapp} \(x\) \\
\hspace{1em} check whether \(x\) is a heap

\# \(h\) \\
\hspace{1em} size of a heap

\textbf{null} \(h\) \\
\hspace{1em} test whether \(h\) is the empty heap

\textbf{members} \(h\) \\
\textbf{list} \(h\) \\
\hspace{1em} list the members of \(h\) in ascending order

\textbf{first} \(h\) \\
\hspace{1em} the first (i.e., smallest) member of \(h\)

\textbf{rmfirst} \(h\) \\
\hspace{1em} remove the first (i.e., smallest) member from \(h\)

\textbf{insert} \(h\ \ x\) \\
\hspace{1em} insert \(x\) into \(h\)

Examples

\begin{verbatim}
> let \(h::\text{heap} = \text{heap} [5,1,3,11,3];
> members \(h\);
\{1,3,3,5,11\}
> first \(h\);
1
> members $ rmfirst \(h\);
\{3,3,5,11\}
\end{verbatim}

2.4.3 Dictionaries

The \texttt{dict.pure} module provides Pure’s dictionary data types based on AVL trees. There are actually four different types to choose from, depending on whether you need ordered or hashed dictionaries and whether multiple values for the same key should be allowed or not.

\textbf{type} \texttt{dict} \\
\hspace{1em} An ordered dictionary. This assumes an ordered key type, i.e., the predicate < must be defined on the keys.
type hdict
A hashed dictionary which works with any (mixture of) key types but stores members in an apparently random order.

type mdict
An ordered dictionary, like dict, which allows multiple values to be associated with the same key.

type hmdict
A multi-valued dictionary, like mdict, but uses hashed keys like hdict.

type xdict
This is just an abstract supertype for matching any kind of dictionary provided by this module.

mdict and hmdict are also colloquially referred to as (ordered or hashed) multidicts. This implementation guarantees that different members for the same key are always kept in the order in which they were inserted, and this is also the order in which they will be retrieved by the members, keys, vals and indexing operations.

The usual comparison predicates (==, -=, <=, < etc.) are defined on all dictionary types, where two dictionaries are considered “equal” (d1==d2) if they both contain the same key=>value pairs, and d1<=d2 means that d1 is a sub-dictionary of d2, i.e., all key=>value pairs of d1 are also contained in d2 (taking into account multiplicities in the multidict case). Ordered dictionaries compare keys using equality (assuming two keys a and b to be equal if neither a<b nor b<a holds), while hashed dictionaries check for syntactical equality (using ===). The associated values are compared using the == predicate if it is defined, falling back to syntactic equality otherwise.

The underlying AVL tree data structure can be found in the avltrees.pure module which is included in the library, but not to be invoked directly.

The AVL tree algorithm has its origin in the SWI-Prolog implementation of association lists. The original implementation was created by R. A. O'Keefe and updated for SWI-Prolog by Jan Wielemaker. For the original source see http://www.swi-prolog.org.

The port from SWI-Prolog and the deletion stuff (rmfirst, rmlast, delete) missing in the Prolog implementation was provided by Jiri Spitz. The generalization of the code to arbitrary combinations of orderedhashed and singlemulti-valued keys was done by Albert Graef.

Imports
To use the operations of this module, add the following import declaration to your program:
using dict;

Operations
emptydict
emptyhdict
emptymdict

2.4.3 Dictionaries
emptyhmdict
    return an empty dictionary

dict xs
hdict xs
mdict xs
hmdict xs
    create a dictionary of the corresponding type either from a list xs of key-value pairs
    in the form key=>value, or from another dictionary; in the latter case the argument is
    converted to a dictionary of the desired target type

dictp d
hdictp d
mdictp d
hmdictp d
    check whether d is a dictionary of the corresponding type

mkdict y xs
mkhdict y xs
mkmdict y xs
mkhmdict y xs
    create a dictionary from a list of keys and a constant value

d1 + d2
    sum: d1+d2 adds the members of d2 to d1

d1 - d2
    difference: d1-d2 removes the members of d2 from d1

d1 * d2
    intersection: d1*d2 removes the members not in d2 from d1

# d
    size of a dictionary (the number of members it contains)

d ! x
    get the value from d by key x; in the case of a multidict this actually returns a list of
    values (which may be empty if d doesn’t contain x)

null d
    test whether d is an empty dictionary

member d x
    test whether d contains a member with key x

members d
list d
    list the members of d (in ascending order for ordered dictionaries)

keys d
    list the keys of d (in ascending order for ordered dictionaries)
vals \( d \)
list the values of \( d \)

first \( d \)
last \( d \)
return the first and the last member of \( d \), respectively

rmfirst \( d \)
rmlast \( d \)
remove the first and the last member from \( d \), respectively

insert \( d \) (x=>y)
update \( d \) x y
insert \( x => y \) into \( d \) (this always adds a new member in a multidict, otherwise it replaces an existing value if there is one); note that update is just a fully curried version of insert, so update \( d \) x y behaves exactly like insert \( d \) (x=>y)

delete \( d \) x
remove x from \( d \) if present (in the multidict case, only the first member with the given key x is removed)

delete_val \( d \) (x=>y)
remove a specific key-value pair \( x => y \) from \( d \) if present (in the multidict case, only the first instance of \( x => y \) is removed); please also see the notes below regarding this operation

delete_all \( d \) x
remove all instances of \( x \) from \( d \) (in the non-multidict case, this is just the same as delete)

---

Note:

- The infix operators +, - and * work like the corresponding set and bag operations (see Sets and Bags), treating dictionaries as collections of key=>val pairs. You can mix arbitrary operand types with these operations, as well as with the comparison operations; the necessary conversions from less general dictionary types (ordered, single-valued) to more general types (hashed, multi-valued) are handled automatically.

- The delete_val function compares values using equality (==) if it is defined, falling back to syntactic equality (===) otherwise. If there is more than one instance of the given value under the given key, the first such instance will be removed (which, if == is defined on the values, may be any instance that compares equal, not necessarily an exact match).

- In the multidict case, delete_val may require linear time with respect to the number of different values stored under the given key. Since this operation is also needed to implement some other multidict operations like comparisons, difference and intersection, these may end up requiring quadratic running times in degenerate cases (i.e., if the majority of members happens to be associated with only very few keys).
Examples

A normal (ordered) dictionary:

```pure
> using dict;
> let d::dict = dict ["foo"=>77,"bar"=>99.1];
> keys d; vals d; members d;
["bar","foo"]
[99.1,77]
["bar"=>99.1,"foo"=>77]
```

Indexing a dictionary works in the usual way, using Pure’s `!` operator. An `out_of_bounds` exception is thrown if the key is not in the dictionary:

```pure
> d!"foo";
77
> d!"baz";
<stdin>, line 5: unhandled exception 'out_of_bounds' while evaluating 'd!"baz"
```

By virtue of the prelude, slicing a dictionary with `!!` also works as expected:

```pure
> d!!["foo","bar","baz"];
[77,99.1]
```

A hashed dictionary can be used with any key values, which are stored in a seemingly random order:

```pure
> let h::hdict = hdict [foo=>77,42=>99.1];
> keys h; vals h; members h;
[42,foo]
[99.1,77]
[42=>99.1,foo=>77]
> h!foo;
77
> h!!keys h;
[99.1,77]
```

Multidicts work in pretty much the same fashion, but allow more than one value for a given key to be stored in the dictionary. In this case, the indexing operation returns a list of all values for the given key, which may be empty if the key is not in the dictionary (rather than throwing an `out_of_bounds` exception):

```pure
> let d::mdict = mdict ["foo"=>77,"bar"=>99.1,"foo"=>99];
> d!"foo"; d!"baz";
[77,99]
[]
```

Slicing thus returns a list of lists of values here:

```pure
> d!!["foo","bar","baz"];
[[77,99],[99.1],[]]
```

To obtain a flat list you can just concatenate the results:
Hashed multidicts provide both key hashing and multiple values per key:

```plaintext
> let h::hmdict = hmdict [foo=>77,42=>99.1,42=>77];
> keys h; vals h; members h;
[42,42,foo]
[99.1,77,77]
[42=>99.1,42=>77,foo=>77]
> h!42;
[99.1,77]
```

There are also some set-like operations which allow you to add/remove the members (key=>val pairs) of one dictionary to/from another dictionary, and to compute the intersection of two dictionaries. For instance:

```plaintext
> let h1 = hmdict [a=>1,b=>2];
> let h2 = hmdict [b=>2,c=>3];
> members (h1+h2);
[a=>1,c=>3,b=>2,b=>2]
> members (h1-h2);
[a=>1]
> members (h1*h2);
[b=>2]
```

It’s possible to mix dictionaries of different types in these operations. The necessary conversions are handled automatically:

```plaintext
> let h1 = hmdict [a=>1,b=>2];
> let h2 = hdict [b=>3,c=>4];
> members (h1+h2);
[a=>1,c=>4,b=>2,b=>3]
```

Note that the result will always be promoted to the most general operand type in such cases (a hashed multidict in the above example). If this is not what you want, you’ll have to apply the necessary conversions manually:

```plaintext
> members (hdict h1+h2);
[a=>1,c=>4,b=>3]
```

### 2.4.4 Sets and Bags

The set.pure module implements Pure’s set data types based on AVL trees. These work pretty much like dictionaries (cf. Dictionaries) but only store keys (called “elements” or “members” here) without any associated data values. Hence sets provide membership tests like dictionaries, but no indexing operations.

There are four variations of this data structure to choose from, depending on whether the set members are ordered or hashed, and whether multiple instances of the same element are allowed (in this case the set is actually called a multiset or a bag).
**Pure Language and Library Documentation, Release 0.68**

**type set**
**type bag**

These implement the ordered set types. They require that members be ordered, i.e., the predicate `<` must be defined on them.

**type hset**
**type hbag**

These implement the hashed set types which don’t require an order of the members. Distinct members are stored in an apparently random order.

**type xset**

This is just an abstract supertype for matching any kind of set or bag provided by this module.

The usual comparison predicates (==, ~=, <=, < etc.) are defined on all set and bag types, where two sets or bags are considered “equal” (m1==m2) if they both contain the same elements, and m1<=m2 means that m1 is a subset or subbag of m2, i.e., all elements of m1 are also contained in m2 (taking into account multiplicities in the multiset case). Ordered sets and bags compare elements using equality (considering two elements a and b to be equal if neither a<b nor b<a holds), while hashed sets and bags check for syntactical equality (using ===).

The underlying AVL tree data structure can be found in the avltrees.pure module which is included in the library, but not to be invoked directly. The AVL tree algorithm has its origin in the SWI-Prolog implementation of association lists and was ported to Pure by Jiri Spitz, see Dictionaries for details.

**Imports**

To use the operations of this module, add the following import declaration to your program:

```pure
using set;
```

**Operations**

```pure
emptyset
emptybag
emptyhset
emptyhbag
```

return an empty set or bag

```pure
set xs
bag xs
hset xs
hbag xs
```

create a set or bag of the corresponding type from a list or another set or bag `xs`; in the latter case the argument is converted to a set or bag of the desired target type

```pure
setp m
bagp m
```
hsetp m
hbagg m
  check whether m is a set or bag of the corresponding type
m1 + m2
  union/sum: m1+m2 adds the members of m2 to m1
m1 - m2
  difference: m1-m2 removes the members of m2 from m1
m1 * m2
  intersection: m1*m2 removes the members not in m2 from m1
# m
  size of a set or bag m
null m
  test whether m is an empty set or bag
member m x
  test whether m contains x
members m
list m
  list the members of m (in ascending order for ordered sets and bags)
first m
last m
  return the first and the last member of m, respectively
rmfirst m
rmlast m
  remove the first and the last member from m, respectively
insert m x
  insert x into m (replaces an existing element in the case of a set)
delete m x
  remove x from m (in the bag case, only the first instance of x is removed)
delete_all m x
  remove all instances of x from m (in the set case, this is just the same as delete)

Note: The infix operators (+, -, *, as well as the comparison operations) allow you to mix arbitrary operand types; the necessary conversions from less general set types (ordered, set) to more general types (hashed, multiset) are handled automatically.

Also note that in the case of sets, + is just the ordinary set union. There are basically two generalizations of this operation to bags, multiset union and multiset sum; + implements the latter. Thus, if a bag m1 contains k1 instances of an element x and a bag m2 contains k2 instances of x, then m1+m2 contains k1+k2 instances of x (rather than max k1 k2 instances, which would be the case for multiset union). Multiset sum is probably more common in

2.4.4 Sets and Bags
practical applications, and also generalizes easily to multidicts (see Dictionaries). However, if multiset union is needed, it can easily be defined in terms of multiset sum as follows:

\[ \text{union } m_1 \ m_2 = m_1 + (m_2 - m_1) \]

### Examples

Some basic set operations:

```plaintext
> let m::set = set [5,1,3,11,3];
> members m;
[1,3,5,11]
> map (member m) (1..5);
[1,0,1,0,1]
> members $ m+set (3..6);
[1,3,4,5,6,11]
> members $ m-set (3..6);
[1,11]
> members $ m*set (3..6);
[3,5]
```

The bag operations work in a similar fashion, but multiple instances are permitted in this case, and each instance counts as a separate member:

```plaintext
> let m::bag = bag [5,1,3,11,3];
> members m;
[1,3,3,5,11]
> members $ delete m 3;
[1,3,5,11]
> members $ insert m 1;
[1,1,3,3,5,11]
> members $ m+bag (3..6);
[1,3,3,3,4,5,5,6,11]
> members $ m-bag (3..6);
[1,3,11]
> members $ m*bag (3..6);
[3,5]
```

As already mentioned, operands of different types can be mixed with the infix operators; the necessary conversions are handled automatically. E.g., here's how you add a set to a bag:

```plaintext
> let m1::bag = bag [5,1,3,11,3];
> let m2::set = set (3..6);
> members (m1+m2);
[1,3,3,4,5,5,6,11]
```

Note that the result will always be promoted to the most general operand type in such cases (a bag in the above example). If this is not what you want, you'll have to apply the necessary conversions manually:
> members (set m1+m2);
[1,3,4,5,6,11]

If set members aren’t ordered then you’ll get an exception when trying to create an ordered set or bag from them:

> set [a,b,c];
<stdin>, line 5: unhandled exception ‘failed_cond’ while evaluating ‘set [a,b,c]’

In such a case hashed sets and bags must be used instead. These work analogously to the ordered sets and bags, but distinct members are stored in an apparently random order:

> members $ hset [a,b,c] + hset [c,d,e];
[c]
> members $ hbag [a,b,c] + hbag [c,d,e];
[a,c,c,b,d,e]

## 2.5 System Interface

This module offers some useful system routines, straight from the C library, as well as some convenience functions for wrapping these up in Pure. Even the “purest” program needs to do some basic I/O every once in a while, and this module provides the necessary stuff to do just that. The operations provided in this module should work (if necessary by a suitable emulation) on all supported systems. Most of the following functions are extensively documented in the C library manual pages, so we concentrate on the Pure-specific aspects here.

### 2.5.1 Imports

To use the operations of this module, add the following import declaration to your program:

```pure
using system;
```

Some functions of the system interface are provided in separate modules; see Regex Matching, Additional POSIX Functions and Option Parsing.

### 2.5.2 Errno and Friends

```pure
erumno
set_errno n
perror msg
strerror n
```

This value and the related routines are indispensable to give proper diagnostics when system calls fail for some reason. Note that, by its very nature, `errno` is a fairly volatile value, don’t expect it to survive a return to the command line in interactive sessions.

Example:
> using system;
> fopen "junk" "r", perror "junk";
> junk: No such file or directory
> fopen "junk" "r"

2.5.3 POSIX Locale

`setlocale` category locale

Set or retrieve the current locale.

Details are platform-specific, but you can expect that at least the categories `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MONETARY`, `LC_NUMERIC` and `LC_TIME` are defined, as well as the following values for the locale parameter: "C" or "POSIX" (the default POSIX locale), "" (the system default locale), and `NULL`, to just query the current locale.

Other string values which can be passed as the locale argument depend on the implementation, please check your local `setlocale(3)` documentation for details. If locale is not `NULL`, the current locale is changed accordingly. The return value is the new locale, or the current locale when passing `NULL` for the locale parameter. In either case, the string returned by `setlocale` is such that it can be passed to `setlocale` to restore the same locale again. In case of an error, `setlocale` fails (rather than returning a null pointer).

Please note that calling this function alters the Pure interpreter’s idea of what the current locale is. When the interpreter starts up, it always sets the default system locale. Unless your scripts rely on a specific encoding, setting the locale to either "C" or "" should always be safe.

Example:

> setlocale LC_ALL NULL;
> "en_US.UTF-8"

2.5.4 Signal Handling

`trap` action sig

Establish or remove Pure signal handlers.

The action parameter of `trap` can be one of the predefined integer values `SIG_TRAP`, `SIG_IGN` and `SIG_DFL`. `SIG_TRAP` causes the given signal to be handled by mapping it to a Pure exception of the form `signal sig`. `SIG_IGN` ignores the signal, `SIG_DFL` reverts to the system’s default handling. See `show -g SIG*` for a list of known signal values on your system.

Note: When the interpreter runs interactively, most standard termination signals (SIGINT, SIGTERM, etc.) are already set up to report corresponding Pure exceptions; if this is not desired, you can use `trap` to either ignore these or revert to the default handlers instead.

See Exception Handling in the Pure Manual for details and examples.
2.5.5 Time Functions

The usual date/time functions from the C library are all provided. This includes some functions to retrieve wallclock and CPU time which usually offer much better resolution than the venerable `time` function.

**time**

Reports the current time in seconds since the **epoch**, 00:00:00 UTC, Jan 1 1970. The result is always a bigint (in fact, the `time` value is already 64 bit on many OSes nowadays).

**gettimeofday**

Returns wallclock time as seconds since the epoch, like `time`, but theoretically offers resolutions in the microsec range (actual resolutions vary, but are usually in the msec range for contemporary systems). The result is returned as a double value (which also limits precision). This function may actually be implemented through different system calls, depending on what’s available on the host OS.

**clock**

Returns the current CPU (not wallclock) time since an arbitrary point in the past, as a machine int. The number of “ticks” per second is given by the `CLOCKS_PER_SEC` constant. Note that this value will wrap around approximately every 72 minutes.

**sleep**

**nanosleep**

Suspend execution for a given time interval in seconds. `sleep` takes integer (int/bigint) arguments only and uses the `sleep()` system function. `nanosleep` also accepts double arguments and theoretically supports resolutions down to 1 nanosecond (again, actual resolutions vary). This function may actually be implemented through different system calls, depending on what’s available on the host OS. Both functions usually return zero, unless the sleep was interrupted by a signal, in which case the time remaining to be slept is returned.

Examples:

```plaintext
> time, sleep 1, time;
1270241703L, 0, 1270241704L
> gettimeofday, nanosleep 0.1, gettimeofday;
1270241709.06338, 0.0, 1270241709.16341
```

Here’s a little macro which lets you time evaluations:

```plaintext
def timex x = y, (t2-t1)/CLOCKS_PER_SEC when
  t1 = clock; y = x; t2 = clock;
end;
```

Example:

```plaintext
> timex (foldl (+) 0 (1..100000));
705082704, 0.07
```

**tzset**
Initialize timezone information.

**variable tzname**
**variable timezone**
**variable daylight**

The timezone information.

The **tzset** function calls the corresponding routine from the C library and initializes the (Pure) variables **tzname**, **timezone** and **daylight** accordingly. See the tzset(3) manual page for details. This routine is also called automatically when the system module is loaded, so you only have to invoke it to get up-to-date information after changes to the locale or the timezone. Example:

```
> tzset;
()
> tzname, timezone, daylight;
["CET","CEST"], -3600, 1
> tzname!daylight;
"CEST"
```

The following functions deal with date/time values in string and “broken-down” time format. See the ctime(3), gmtime(3), localtime(3), mktime(3), asctime(3), strftime(3) and strptime(3) manual pages for details.

**ctime**
Convert a time value as returned by the **time** function to a string in local time.

**gmtime**
**localtime**

Convert a time value to UTC or local time in “broken-down” form (a static pointer to a **tm** struct containing a bunch of **int** fields) which can then be passed to the **asctime** and **strftime** functions, or to **int_matrix** if you want to convert the data to a matrix; see the example below.

**mktime**
Converts broken-down time to a time value (seconds since the epoch). As with **time**, the result is always a bigint.

**asctime**
**strftime**

Format broken-down time as a string. **strftime** also uses a format string supplied by the user, see below for a list of the most important conversion specifiers.

**strptime**
Parse a date/time string **s** according to the given format (using more or less the same format specifiers as the **strftime** function) and store the broken-down time result in the given **tm** struct. This function may fail, e.g., if **strptime** finds an error in the format string. Otherwise it returns the part of the string which wasn’t processed, see the example below.

Examples:
> let t = time; t;
    1270239790L
> let tm = localtime t; tm;
#<pointer 0x7ff97ecbdde0>
> mktime tm;
    1270239790L
> asctime tm;
"Fri Apr  2 22:23:10 2010\n"
> int_matrix 9 tm;
    {10,23,22,3,110,5,91,1}
> strftime "%c" tm;
"Fri 02 Apr 2010 10:23:10 PM CEST"
> strftime ans "%c" tm, int_matrix 9 tm;
"CEST",{10,23,22,3,110,5,91,1}

In the above example, `strptime` was given a static pointer to a `tm` struct returned by `localtime`. This always works, but in some situations it may be preferable to allocate dynamic storage instead. This storage should be properly initialized (zeroed out) before passing it to `strptime`, since `strptime` only stores the values specified (at least in principle; please consult your local C library documentation for details). Also note that while POSIX only specifies nine `int` fields in a `tm` struct, depending on the host operating system the struct may contain additional public and private fields. The actual size of a `tm` struct is given by the `SIZEOF_TM` constant, so a safe way to allocate suitable dynamic storage for the `strptime` function is as follows:

> let tm = pointer_cast "int*" $ calloc 1 SIZEOF_TM;
> strftime "4/2/10" "%D" tm, int_matrix 9 tm;
"",{0,0,0,2,3,110,5,91,0}

Instead of explicitly allocating dynamic storage and converting it to a Pure matrix later, you can also invoke `strptime` directly with an int matrix of sufficient size:

> let tm = imatrix (SIZEOF_TM div SIZEOF_INT + 1);
> strftime "4/2/10" "%D" tm, take 9 tm;
"",{0,0,0,2,3,110,5,91,0}

Last but not least, to make calling `strptime` more convenient, you can supply your own little wrapper function which takes care of allocating the storage, e.g.:

```pure
mystrptime s format = s,take 9 tm when
    tm = imatrix (SIZEOF_TM div SIZEOF_INT + 1);
    s = strftime s format tm;
end;
```

```pure
> mystrptime "4/2/10" "%D";
"",{0,0,0,2,3,110,5,91,0}
```

Here is a list of some common format specifiers which can be used with the `strftime` and `strptime` routines. These are all specified by POSIX and should thus be available on most platforms. Note that many more formats are usually supported than what is listed here, so please consult your local manual pages for the complete list.

2.5.5 Time Functions
• `%d, %m, %y`: Day of the month, month and year as decimal two-digit numbers.
• `%Y`: The year as a four-digit number which includes the century.
• `%H, %M, %S`: Hours (range 00 to 23), minutes and seconds as decimal two-digit numbers.
• `%I`: The hours on a 12-hour clock (range 01 to 12).

The following formats are locale-dependent:
• `%a, %A`: Abbreviated and full weekday name.
• `%b, %B`: Abbreviated and full month name.
• `%p`: AM or PM. %P is the same in lowercase (strftime only).

There are also some useful meta-formats which specify various combinations of the above:
• `%c`: The preferred date and time representation for the current locale.
• `%D`: The American date format (%m/%d/%y).
• `%F`: The ISO 8601 date format (%Y-%m-%d). (This is generally supported by strftime only, but strftime from GNU libc has it.)
• `%r`: The time in AM/PM notation (%I:%M:%S %p).
• `%R`: The time in 24-hour notation (%H:%M).
• `%T`: The time in 24-hour notation, including seconds (%H:%M:%S).

In addition, %% denotes a literal % character, %n newlines and %t tabs. (For strftime the latter two are synonymous and match arbitrary whitespace.)

Windows users should note that strftime isn’t natively supported there. A basic emulation is provided by the Pure runtime, but at present this only supports the C locale.

2.5.6 Process Functions

The following process functions are available on all systems. (Some additional process-related functions such as fork, kill, wait and waitpid are available in the posix module, see Additional POSIX Functions.)

```
system cmd
    Execute a shell command.
execv prog argv
execvp prog argv
execve prog argv envp
    Execute a new process. prog denotes the name of the executable to be run, argv the argument vector (which repeats the program name in the first component), and envp a vector of environment strings of the form "var=value". The execv function executes the program prog exactly as given, while execvp also performs a path search. The execve function is like execv, but also specifies an environment to be passed to the process. In either case, the new process replaces the current process. For convenience,
```
both argv and envp can be specified as a Pure string vector or a list, which is automatically translated to the raw, NULL-terminated C string vectors (i.e., char**) required by the underlying C functions.

```plaintext
spawnv mode prog argv
spawnvp mode prog argv
spawnve mode prog argv envp
```

Spawn a new child process. These work like the corresponding MS Windows functions; on Un*x systems this functionality is implemented using a combination of fork and execv. The arguments are the same as for the execv functions, except that there’s an additional mode argument which specifies how the process is to be executed: P_WAIT waits for the process to finish, after which spawnv returns with the exit status of the terminated child process; P_NOWAIT makes spawnv return immediately, returning the process id; and P_OVERLAY causes the child process to replace its parent, just like with execv. (On Windows, there’s an additional P_DETACH flag which works like P_NOWAIT but also turns the child process into a background task.)

Note that, in addition, the prelude provides the exit function which terminates the program with a given exit code, cf. Other Special Primitives.

Examples:

```plaintext
> system "pwd";
/home/ag/svn/pure-lang/trunk/pure/lib
0
> spawnvp P_WAIT "pwd" ["pwd"]; 
/home/ag/svn/pure-lang/trunk/pure/lib
0
> spawnv P_WAIT "/bin/sh" ["/bin/sh","-c","pwd"]; 
/home/ag/svn/pure-lang/trunk/pure/lib
0
```

### 2.5.7 Basic I/O Interface

Note that this module also defines the standard I/O streams stdin, stdout and stderr as variables on startup. These are ready to be used with the operations described below. Also note that for convenience some of the following routines are actually Pure wrappers, rather than just providing the raw C library routines.

```plaintext
variable stdin
variable stdout
variable stderr
```

The standard I/O streams.

```plaintext
fopen name mode
popen cmd mode
```

Open a file or a pipe. These take care of closing a file object automagically when it’s garbage-collected, and fail (instead of returning a null pointer) in case of error, so that you can provide any desired error handling simply by adding suitable equations.

```plaintext
fdopen fd mode
```
 Associates a file object with a given existing file descriptor. Otherwise works like \texttt{fopen}, so the resulting file is closed automatically when it’s garbage-collected.

\textbf{freopen} \texttt{path mode fp}

Reopens a file object. The existing file object is closed. Otherwise works like \texttt{fopen}, so the resulting file is closed automatically when it’s garbage-collected.

\textbf{fclose} \texttt{fp}

\textbf{pclose} \texttt{fp}

Close a file or a pipe.

\textbf{tmpfile}

Creates a unique temporary file (opened in "w+b" mode) which gets deleted automatically when it is closed or the file object gets garbage-collected.

\textbf{feof} \texttt{fp}

\textbf{ferror} \texttt{fp}

\textbf{clearerr} \texttt{fp}

Check the end-of-file and error bits. \texttt{clearerr} clears the error bit.

\textbf{fileno} \texttt{fp}

Returns the file descriptor associated with the given file.

\textbf{fflush} \texttt{fp}

Flushes the given file (or all open files if \texttt{fp} is \texttt{NULL}).

\textbf{fgets} \texttt{fp}

\textbf{gets}

Pure wrappers for the C \texttt{fgets} and \texttt{gets} functions which handle the necessary buffering automatically.

\textbf{fget} \texttt{fp}

A variation of \texttt{fgets} which slurps in an entire text file at once.

\textbf{fputs} \texttt{s fp}

\textbf{puts} \texttt{s}

Output a string to the given file or \texttt{stdout}, respectively. These are just the plain C functions. Note that \texttt{puts} automatically adds a newline, while \texttt{fputs} doesn’t. Hmm.

\textbf{fread} \texttt{ptr size nmemb fp}

\textbf{fwrite} \texttt{ptr size nmemb fp}

Binary read/writes. Here you’ll have to manage the buffers yourself. See the corresponding manual pages for details.

\textbf{fseek} \texttt{fp offset whence}

\textbf{ftell} \texttt{fp}

\textbf{rewind} \texttt{fp}

Reposition the file pointer and retrieve its current value. The constants \texttt{SEEK_SET}, \texttt{SEEK_CUR} and \texttt{SEEK_END} can be used for the \texttt{whence} argument of \texttt{fseek}. The call \texttt{rewind \texttt{fp} is equivalent to fseek \texttt{fp 0 SEEK_SET}} (except that the latter also returns a result code). See the corresponding manual pages for details.

\textbf{setbuf} \texttt{fp buf}
**setvbuf** fp buf mode size

Set the buffering of a file object, given as the first argument. The second argument specifies the buffer, which must be a pointer to suitably allocated memory or **NULL**. The **mode** argument of **setvbuf** specifies the buffering mode, which may be one of the predefined constants **_IONBF**, **_IOLBF** and **_IOFBF** denoting no buffering, line buffering and full (a.k.a. block) buffering, respectively; the **size** argument denotes the buffer size.

For **setbuf**, the given buffer must be able to hold **BUFSIZ** characters, where **BUFSIZ** is a constant defined by this module. **setbuf** fp buf is actually equivalent to the following call (except that **setvbuf** also returns an integer return value):

```c
setvbuf fp buf (if null buf then _IONBF else _IOFBF) BUFSIZ
```

Please see the **setbuf(3)** manual page for details.

Examples:

```c
> puts "Hello, world!";
Hello, world!
14

> map fileno [stdin,stdout,stderr];
[0,1,2]

> let fp = fopen "/etc/passwd" "r";
> fgets fp; "at:x:25:25:Batch jobs daemon:/var/spool/atjobs:/bin/bash\n"
> fgets fp; "avahi:x:103:104:User for Avahi:/var/run/avahi-daemon:/bin/false\n"
> ftell fp;
121L
> rewind fp;
()
> fgets fp;
"at:x:25:25:Batch jobs daemon:/var/spool/atjobs:/bin/bash\n"

> split "\n" $ fget $ popen "ls *.pure" "r";
["array.pure","dict.pure","getopt.pure","heap.pure","math.pure",
"matrices.pure","prelude.pure","primitives.pure","quasiquote.pure",
"set.pure","strings.pure","system.pure","*"]
```

C-style formatted I/O is provided through the following wrappers for the C **printf** and **scanf** functions. These wrapper functions take or return a tuple of values and are fully type-safe, so they should never segfault. All basic formats derived from %cdioux, %efg, %s and %p are supported, albeit without the standard length modifiers such as h and l, which aren’t of much use in Pure. (However, in addition to C **printf** and **scanf**, the Pure versions also support the modifiers Z and R of the **GMP** and **MPFR** libraries, which are used for converting multiprecision integer and floating point values, as shown in the examples below.)

**printf** format args
**fprintf** fp format args
Print a formatted string to `stdout` or the given file, respectively. Normally, these functions return the result of the underlying C routines (number of characters written, or negative on error). However, in case of an abnormal condition in the wrapper function, such as argument mismatch, they will throw an exception. (In particular, an `out_of_bounds` exception will be thrown if there are not enough arguments for the given format string.)

**sprintf** format args
Print a formatted string to a buffer and return the result as a string. Note that, unlike the C routine, the Pure version just returns the string result in the case of success; otherwise, the error handling is the same as with `printf` and `fprintf`. The implementation actually uses the C routine `snprintf` for safety, and a suitable output buffer is provided automatically.

**scanf** format

**fscanf** fp format
Read formatted input from `stdin` or the given file, respectively. These normally return a tuple (or singleton) with the converted values. An exception of the form `scanf_error ret`, where `ret` is the tuple of successfully converted values (which may be less than the number of requested input items), is thrown if end-of-file was met or another error occurred while still reading. The handling of other abnormal conditions is analogous to `printf` et al. Also note that this implementation doesn’t accept any of the standard length modifiers; in particular, floating point values will always be read in double precision and you just specify e, g etc. for these. The “assignment suppression” flag * is understood, however; the corresponding items will not be returned.

**sscanf** s format
This works exactly like `fscanf`, but input comes from a string (first argument) rather than a file.

Examples:

```plaintext
> do (printf "%s%d\n" ["foo", 5], ["catch", 22]);
foo5 catch22
>
> sscanf "foo 5 22" "%s %d %g";
"foo", 5, 22.0
```

As mentioned above, special argument formats are provided for bigints and multiprecision floats:

```plaintext
> sscanf "a(5) = 1234" "a(%d) = %Zd";
5,1234L
> sprintf "a(%d) = %Zd" ans;
"a(5) = 1234"
>
> using mpfr;
> mpfr_set_default_prec 113;
()
> printf "pi = %0.30Rg\n" (4*atan (mpfr 1));
```

---

**2.5 System Interface**
pi = 3.14159265358979323846264338328

There are a number of other options for these conversions, please check the GMP and MPFR documentation for details.

Note: In contrast to bigints, multiprecision floats aren’t directly supported by the Pure language. If you would like to use these numbers, you’ll have to install the mpfr addon module which is not included in the standard library yet. Also note that, at the time of this writing, MPFR only provides formatted output, so multiprecision floats are not supported by the scanf functions. To work around this limitation, it is possible to read the number as a string and then convert it using the mpfr function.

2.5.8 Stat and Friends

stat path
Return information about the given file. This is a simple wrapper around the corresponding system call, see the stat(2) manual page for details. The function returns a tuple with the most important fields from the stat structure, in this order: st_dev, st_ino, st_mode, st_nlink, st_uid, st_gid, st_rdev, st_size, st_atime, st_mtime, st_ctime. Among these, st_mode, st_nlink, st_uid and st_gid are simple machine integers, the rest is encoded as bigints (even on 32 bit platforms).

lstat path
Return information about the given symbolic link (rather than the file it points to). On systems where this function isn’t supported (e.g., Windows), lstat is identical to stat.

fstat fp
Return information about the given file object. Same as stat, but here the file is given as a file pointer created with fopen (see Basic I/O Interface above). Note that the corresponding system function actually takes a file descriptor, so the Pure implementation is equivalent to the C call fstat(fileno(fp)). This function might not be supported on all platforms.

For average applications, the most interesting fields are st_mode and st_size, which can be retrieved with stat filename!!![2,7]. Note that to facilitate access to the st_mode field, the usual masks and bits for file types (S_IFMT, S_IFREG, etc.) and permissions (S_ISUID, S_ISGID, S_IRWXU, etc.) are defined as constants by this module. Use the command show -g S_* in the interpreter to get a full list of these. Other interesting fields are st_atime, st_mtime and st_ctime, which can be accessed using stat filename!!![8..10]. The values of these fields are the times of last access, last modification and creation, respectively, which can be decoded using the appropriate time functions like ctime or strftime, see Time Functions.

Examples:

> stat "/etc/passwd";
64773L,9726294L,33188,1,0,0,0L,1623L,1250373163L,1242692339L,1242692339L
> stat "/etc/passwd"!7; // file size
> strftime "%c" $ localtime $ stat "/etc/passwd"!10; // creation time
"Tue 19 May 2009 02:18:59 AM CEST"
> sprintf "0%o" $ stat "/etc/passwd"!2 and not S_IFMT; // permissions
"0644"
> stat "/etc/passwd"!2 and S_IFMT == S_IFREG; // this is a regular file
1
> stat "/etc"!2 and S_IFMT == S_IFDIR; // this is a directory
1

2.5.9 Reading Directories

`readdir name`

Read the contents of the given directory and return the names of all its entries as a list.

Example:

> readdir "/home";
["ag", ".", "."]

2.5.10 Shell Globbing

`fnmatch pat s flags`

Returns a simple truth value (1 if pat matches s, 0 if it doesn’t), instead of an error code like the C function.

`glob pat flags`

Returns a Pure list with the matches (unless there is an error in which case the integer result code of the underlying C routine is returned).

The available flag values and glob error codes are available as symbolic FNM_* and GLOB_* constants defined as variables in the global environment. See the fnmatch(3) and glob(3) manpages for the meaning of these.

Example:

> glob "*.pure" 0;
["array.pure","dict.pure","getopt.pure","heap.pure","math.pure",
"matrices.pure","prelude.pure","primitives.pure","set.pure",
"strings.pure","system.pure"]

2.5.11 Regex Matching

Please note that, as of Pure 0.48, this part of the system interface is not included in the system module any more, but is provided as a separate regex module which can be used independently of the system module. To use the operations of this module, add the following import declaration to your program:

`using regex;`
Since the POSIX regex functions (`regcomp` and `regexec`) have a somewhat difficult calling sequence, this module provides a couple of rather elaborate high-level wrapper functions for use in Pure programs. These are implemented in terms of a low-level interface provided in the runtime. (The low-level interface isn’t documented here, but these functions are also callable if you want to create your own regular expression engines in Pure. You might wish to take a look at the implementation of the high-level functions in regex.pure to see how this can be done.)

`regex` function:

```
regex pat cflags s eflags
Compiles and matches a regex in one go, and returns the list of submatches (if any).
```

**Parameters**

- `pat` (string) – the regular expression pattern
- `cflags` (int) – the compilation flags (bitwise or of any of the flags accepted by `regcomp(3)`)
- `s` (string) – the subject string to be matched
- `eflags` (int) – the matching execution flags (bitwise or of any of the flags accepted by `regexec(3)`)

Symbolic REG_ constants are provided for the different flag values, see the `regcomp(3)` manpage for an explanation of these. (Please note that these symbolic “constants” aren’t really constants, but are actually implemented as variables, since their values may depend on which underlying regex library is being used. Please check Perl Regex Compatibility below for details.)

Two particularly important compilation flags (to be included in the `cflags` argument) are REG_NOSUB, which prevents submatches to be computed, and REG_EXTENDED, which switches `regex` from “basic” to “extended” regular expressions so that it understands all the regular expression elements of `egrep(1)` in the pattern argument.

Depending on the flags and the outcome of the operation, the result of this function can take one of the following forms:

- `regerr code msg`: This indicates an error during compilation of the pattern (e.g., if there was a syntax error in the pattern). `code` is the nonzero integer code returned by `regcomp`, and `msg` is the corresponding error message string, as returned by `regerror`. You can redefine the `regerr` function as appropriate for your application (e.g., if you’d like to print an error message or throw an exception).

- 0 or 1: Just a truth value indicates whether the pattern matched or not. This will be the form of the result if the REG_NOSUB flag was specified for compilation, indicating that no submatch information is to be computed.

- 0 (indicating no match), or 1 (indicating a successful match), where the latter value is followed by a tuple of (pos, substr) pairs for each submatch. This will be the form of the result only if the REG_NOSUB flag was not specified for compilation, so that submatch information is available.
Note that, according to POSIX semantics, a return value of 1 does not generally mean that the entire subject string was matched, unless you explicitly tie the pattern to the beginning (\^) and end (\$) of the string.

If the result takes the latter form, each (pos, substr) pair indicates a portion of the subject string which was matched; pos is the position at which the match starts, and substr is the substring (starting at position pos) which was matched. The first (pos, substr) pair always indicates which portion of the string was matched by the entire pattern, the remaining pairs represent submatches for the parenthesized subpatterns of the pattern, as described on the regcomp(3) manual page. Note that some submatches may be empty (if they matched the empty string), in which case a pair (pos, "") indicates the (nonnegative) position pos where the subpattern matched the empty string. Other submatches may not participate in the match at all, in which case the pair (-1, ") is returned.

The following helper functions are provided to analyze the result returned by regex.

reg_result res
    Returns the result of a regex call, i.e., a regerr term if compilation failed, and a flag indicating whether the match was successful otherwise.

reg_info res
    Returns the submatch info if any, otherwise it returns ()

reg n info
    Returns the nth submatch of the given submatch info, where info is the result of a reg_info call.

regs info
    Returns all valid submatches, i.e., the list of all triples (n, p, s) for which reg n == (p, s) with p>=0.

In addition, the following convenience functions are provided to perform global regex searches, to perform substitutions, and to tokenize a string according to a given delimiter regex.

regex f pat cflags s eflags
    Perform a global regular expression search. This routine will scan the entire string for (non-overlapping) instances of the pattern, applies the given function f to the reg_info for each match, and collects all results in a list. Note: Never specify the REG_NOSUB flag with this function, it needs the submatch info.

regexg f pat cflags s eflags
    This works like regex, but allows overlapping matches.

regsub f pat cflags s eflags
    Replaces all non-overlapping instances of a pattern with a computed substitution string. To these ends, the given function f is applied to the reg_info for each match. The result string is then obtained by concatenating f info for all matches, with the unmatched portions of the string in between. To make this work, f must always return a string value; otherwise, regsub throws a bad_string_value exception.
**regsplit** pat cflags s eflags

Splits a string into constituents delimited by substrings matching the given pattern.

Please note that these operations all operate in an eager fashion, i.e., they process the entire input string in one go. This may be unwieldy or at least inefficient for huge amounts of text. As a remedy, the following lazy alternatives are available:

**regexgs** f pat cflags s eflags

**regexggs** f pat cflags s eflags

**regrsplits** pat cflags s eflags

These work like **regexg**, **regexgg** and **regsplit** above, but return a stream result which enables you to process the matches one by one, using “call by need” evaluation.

### Basic Examples

Let’s have a look at some simple examples:

```newlisp
> let pat = "[:alpha:][[:alnum:]]*";
> let s = "1var foo 99 BAR $%&";

Simple match:

```
> regex pat 0 s 0;
1,1,"var"
```

Same without match info:

```
> regex pat REG_NOSUB s 0;
1
```

Global match, return the list of all matches:

```
> regexg id pat 0 s 0;
[(1,"var"),(5,"foo"),(12,"BAR")]
```

Same with overlapping matches:

```
> regexgg id pat 0 s 0;
(13,"AR"),(14,"R")]
```

Note that **id** (the identity function) in the examples above can be replaced with an arbitrary function which processes the matches. For instance, if we only want the matched strings instead of the full match info:

```
> regexg (!1) pat 0 s 0;
["var","foo","BAR"]
```

Lazy versions of both **regexg** and **regexgg** are provided which return the result as a stream instead. These can be processed in a “call by need” fashion:

```
> regexgs id pat 0 s 0;
(1,"var"):<thunk 0x7fb1b7976750>
```
Let’s verify that the processing is really done lazily:

```plaintext
> using system;
> test x = printf "got: %s\n" (str x) $$ x;
> let xs = regexgs test pat 0 s 0;
> last xs;
```

As you can see, the first match is produced immediately, while the remaining matches are processed as the result stream is traversed. This is most useful if you have to deal with bigger amounts of text. By processing the result stream in a piecemeal fashion, you can avoid keeping the entire result list in memory. For instance, compare the following:

```plaintext
> let s2 = fget $ fopen "system.pure" "r";
> stats -m
> #regexgs id pat 0 s2 0;
7977
0.18s, 55847 cells
> #regexgs id pat 0 s2 0;
7977
0.12s, 20 cells
```

### Regex Substitutions and Splitting

We can also perform substitutions on matches:

```plaintext
> regsub (sprintf "<%d:%s>\n") pat 0 s 0;
"1<1:var> <5:foo> 99 <12:BAR> $%&"
```

Or split a string using a delimiter pattern (this uses an egrep pattern):

```plaintext
> let delim = "[:space:]+";
> regsplit delim REG_EXTENDED s 0;
["1var","foo","99","BAR","$%&"]
> regsplit delim REG_EXTENDED "The quick brown fox" 0;
["The","quick","brown","fox"]
```

The `regsplit` operation also has a lazy variation:

```
> regsplits "[:space:]+" REG_EXTENDED "The quick brown fox" 0;
"The":# thunk 0x7fb1b79775b0>
> last ans;
"fox"
```
Empty Matches

Empty matches are permitted, too, subject to the constraint that at most one match is reported for each position (which also prevents looping). And of course an empty match will only be reported if nothing else matches. For instance:

```
> regexgid "" REG_EXTENDED "foo" 0;
[(0,""),(1,""),(2,""),(3,"")]

> regexgid "o*" REG_EXTENDED "foo" 0;
[(0,""),(1,"oo"),(3,"")]

> regexggid "o*" REG_EXTENDED "foo" 0;
[(0,""),(1,"oo"),(2,"o"),(3,"")]
```

This also works when substituting or splitting:

```
> regsub (cst "") "" REG_EXTENDED "some text" 0;
" some text"

> regsub (cst "") "?" REG_EXTENDED "some text" 0;
" some text"

> regsplit "" REG_EXTENDED "some text" 0;
["","s","o","m","e","t","e","x","t",""]

> regsplit "?" REG_EXTENDED "some text" 0;
["","s","o","m","e","t","e","x","t",""]
```

Submatches

Parenthesized subexpressions in a pattern yield corresponding submatch information, which is useful if we need to retrieve the text matched by a given subexpression. For instance, suppose we want to parse environment lines, such as those returned by the shell’s `set` command. These can be dissected using the following regex:

```
> let env_pat = "^([^=]+)=(.*)$";
> let env_flags = REG_EXTENDED or REG_NEWLINE;
>
> regex env_pat env_flags "SHELL=/bin/sh" 0;
1,0,"SHELL=/bin/sh",0,"SHELL"

```

Note that we again used an extended regex here, and we also added the REG_NEWLINE flag so that we properly deal with multiline input. The desired information is in the 4th and 6th element of the submatch info, we can retrieve that as follows:

```
> parse_env s = regexg (\info -> info!3 => info!5) env_pat env_flags s 0;
> parse_env "SHELL=/bin/sh\nHOME=/home/bar\n";
["SHELL"="/bin/sh","HOME="/home/bar"]
```

We can get hold of the real process environment as follows:

```
> using system;
> let env = parse_env $ fget $ popen "set" "r";
> #env;
109
> head env;
"BASH="/usr/bin/sh"
```

2.5.11 Regex Matching
Just for the fun of it, let’s convert this to a record, providing easy random access to the environment variables:

````
> let env = record env;
> env!!["SHELL", "HOME"];
{"/bin/bash", "/home/ag"}
```

**Perl Regex Compatibility**

Pure 0.64 and later can be built with support for Perl-style regular expressions in the runtime. This is disabled by default, but you can build the interpreter with the `--with-pcre` configure option to enable it. You need to have the pcreposix library installed to make that work, see http://www.pcre.org/.

Once this option is enabled, Pure’s regex operations will work as discussed above, except that they will now understand Perl-style regular expressions, as implemented by the libpcre library, instead of the (much more limited) POSIX syntax. For instance, you can now write:

````
> using regex;
> regex "(?:Bob says: (\w+))" 0 "Bob says: Go" 0;
1,0,"Bob says: Go",10,"Go"
```

Note that in Perl-style regexes the `(?:...)` construct indicates a non-capturing group, so that the above invocation returns just a single submatch for the second `(\w+)` group.

A discussion of Perl regexes is beyond the scope of this manual, so you may want to refer to http://www.rexegg.com/ for more information or read a good book on the subject.

Pure scripts can detect whether Perl regexes are enabled by inspecting the value of the `pcre_version` variable. This variable will only be defined if the interpreter was built with the `--with-pcre` configure option, in which case its value is the version number of the libpcre library as a string.

Please note that enabling this option will change the meaning of some constructs in the regular expression syntax, even if you don’t actually use any of the Perl-specific extensions. It’s possible to write Pure scripts which work with either libpcre or the default (POSIX) regex library, but you need to be aware of the discrepancies. The most notable differences are that `REG_EXTENDED` is always enabled and the treatment of newlines is different in some situations if `REG_NEWLINE` is used; please check the pcreposix(3) manual page for details. Also, the `REG_*` “constants” differ between libpcre and the POSIX regex functions, so you should never hard-code these into batch-compiled scripts (simply avoid `const` definitions involving these values, then you should be fine).

### 2.5.12 Additional POSIX Functions

**Platforms:** Mac, Unix The posix module provides some additional POSIX functions not available on all supported systems. (In particular, none of these functions are provided on MS Windows.) You can load this module in addition to the system module if you need the additional functionality. To use the operations of this module, add the following import declaration to your program:
using posix;

The following operations are provided. Please see the appropriate POSIX manual pages for a closer description of these functions.

fork
Fork a new process.

getpid
getppid
Get the process id of the current process and its parent process, respectively.

wait status
waitpid pid status options
Wait for any child process, or the given one. The status argument must be a pointer to an int value, which is used to return the status of the child process.

kill pid sig
Send the given signal to the given process.

raise sig
Raise the given signal in the current process.

pause
Sleep until a signal is caught.

2.5.13 Option Parsing

This is a quick-and-dirty replacement for the GNU getopt functions, ported from the Q library. To use the operations of this module, add the following import declaration to your program:

using getopt;

The following operation is provided:

getopt opts args
Parse options as given by opts in the command line arguments args, return the parsed options along with a list of the remaining (non-option) command line arguments.

The getopt function takes two arguments: opts, a list of option descriptions in the format described below, and args, a list of strings containing the command line parameters to be parsed for options. The result is a pair (opts_return, args_return) where opts_return is a list of options and their values, and args_return is the list of remaining (non-option) arguments. Options are parsed using the rules of GNU getopt(1). If an invalid option is encountered (unrecognized option, missing or extra argument, etc.), getopt throws the offending option string as an exception.

The opts_return value is a list of “hash pairs” opt=>val where opt is the (long) option name (as given by the long_opt field given in the opts argument, see below) and val is the corresponding value (() if none). Note that this format is ready to be passed to the dict or hdict function, cf. Dictionaries, which makes it easy to retrieve option values or check for
the presence of options. (As of Pure 0.41, you can also just convert the list to a record and employ the record functions to access the option data, cf. Record Functions.)

The `opts` argument of `getopt` must be a list of triples `(long_opt, short_opt, flag)`, where `long_opt` denotes the long option, `short_opt` the equivalent short option, and `flag` is one of the symbolic integer values `NOARG`, `OPTARG` and `REQARG` which specifies whether the option has no argument, an optional argument or a required argument, respectively. Either `long_opt` or `short_opt` should be a string value of the form `"-abc"` or `"-x"`, respectively. Note that since the `long_opt` value is always used to denote the corresponding option in the `opts_return` list, you always have to specify a sensible value for that field. If no separate long option name is needed, you can specify the same value as in the `short_opt` field, or some other convenient value (e.g., an integer) which designates the option. Conversely, to indicate that an option has no short option equivalent, simply specify an empty option string for the `short_opt` field.

Examples:

```plaintext
> let opts = [("--help", "-h", NOARG), // no argument
             ("--version", "", NOARG), // no short option
             ("--filename", "-f", REQARG), // required argument
             ("--count", "-n", OPTARG)]; // optional argument
> getopt opts ["foo", "-h", "--filename", "bar", "-n0", "baz"];
["--help"=>(),"--filename"=>"bar","--count"=>"0"],["foo","baz"]
> catch invalid_option $ getopt opts ["-h","-v"];
invalid_option "-v"
> getopt opts [foo, "-h", bar];
["--help"=>()],[foo,bar]
```

As the last example shows, non-option arguments (as well as option values specified as separate arguments) can actually be any values which are just copied to the result lists as is.
pure-avahi: Pure Avahi Interface

Version 0.4, April 11, 2018

Albert Gräf <aggraef@gmail.com>

This is a simple interface to Avahi, a Zeroconf implementation for Linux and other Un*x systems. The module lets you publish and query Zeroconf network services using Avahi, allowing you to establish connections for various kinds of TCP and UDP network services without having to manually configure network addresses. It is typically used along with the sockets module which lets you create the network connections discovered with avahi.

To keep things simple and easy to use, the module only exposes the most essential functionality of Avahi right now, but the provided functions should hopefully be sufficient for most programs which require interoperability with other Avahi or Apple Bonjour applications. One known limitation is that the module allows you to publish and discover services in the default Avahi domain only. Typically this is the local domain, limiting you to services in the local network. However, this should cover most common uses of Zeroconf.

There’s a companion bonjour module which implements the same API for Bonjour, Apple’s Zeroconf implementation. Since both modules implement the same functions, albeit in different namespaces, they can be used as drop-in replacements for each other. We also offer a compatibility module named zeroconf which can be used with either pure-avahi or pure-bonjour in a transparent fashion, so that no source changes are needed when switching the underlying implementation; please check the zeroconf.pure script included in the sources for details.

This module is in its early stages, so it may still contain bugs or lack some features. Please report bugs on the issue tracker at the Pure Bitbucket site, and use the Pure mailing list for general discussion of the module.

3.1 Copying

Copyright (c) 2014 by Albert Graef.
pure-avahi is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-avahi is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

3.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-avahi-0.4.tar.gz.

Run `make` to compile the module and `make install` (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure and Avahi installed. The latter should be readily available on most Linux systems, and ports are available for BSD systems as well.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually, please check the Makefile for details.

Please note that the zeroconf.pure compatibility module is not installed by default, so you may want to copy it to the Pure library directory if needed.

3.3 Usage

To use the operations of this module, you need to have Avahi installed and the Avahi daemon running on your system. The details of this depend on the particular system that you use, so please consult the documentation of your Linux or BSD distribution for instructions.

The following import declaration loads the functions of the avahi module in your Pure script:

```pure
using avahi;
```

All operations are in the `avahi` namespace, so you might want to add the following declaration to access the functions using their unqualified identifiers:

```pure
using namespace avahi;
```

3.4 Publishing Services

These functions allow you to advertise a network service using Avahi, so that the service can be discovered by other applications participating in the Zeroconf protocol. Each service has a name (a string which uniquely identifies the service), a type (indicating the application and transport protocols utilized by the service) and a port number (TCP or UDP port number, depending on the service type). The service type normally takes the form `_app._tcp` (for
TCP services) or `_app._udp` (for UDP), where `app` specifies the protocol of the particular application (such as `_ipp` for network-connected printers, or `_osc` for applications speaking the OSC a.k.a. Open Sound Control protocol).

**avahi::publish** name stype port

Advertise a service in the local domain, given by its name (a string), service type (a string) and (TCP or UDP) port number (an integer). Note that this operation is actually carried out asynchronously. Use **avahi::check** below to wait for and report the result of the operation. The returned result is a pointer to the service object which can be passed to the following operations, or NULL in case of error. (A NULL pointer can be passed safely to **avahi::check**; it will fail in this case.) The service will be unpublished automatically when the service object is garbage-collected.

**avahi::check** service

Check for the result of a `avahi::publish` operation. This blocks until a result is available. A negative integer value indicates failure (in this case the result is the Avahi error code). Otherwise the result is a triple with the actual service name, type and port. Note that the name may be different from the one passed to `avahi::publish` if there was a name collision with another service. Such collisions are resolved automatically by tacking on a suffix of the form `#n` to the service name.

### 3.5 Discovering Services

These functions let you discover services of a given service type. For each (resolvable) service you’ll be able to retrieve the corresponding network address and port, which is what you’ll need to actually open a network connection to communicate with the service.

**avahi::browse** stype

Browse available services of a given type in the local domain. This operation is carried out asynchronously; use **avahi::avail** below to check whether new information is available, and **avahi::get** to retrieve the actual service list. The result returned by **avahi::browse** is a pointer to the browser object which can be passed to the following operations, or NULL in case of error. (A NULL pointer can be passed safely to the other operations; they will fail in this case.) Any resources allocated to the browser will be released automatically when the browser object is garbage-collected.

**avahi::avail** browser

Check whether the service information was updated since the last invocation of **avahi::get**. Returns an integer (truth value), which may also be negative (indicating the Avahi error code) in case of error.

**avahi::get** browser

Retrieve the current list of services. Each list entry is a tuple with the name, type, domain, IP address (all string values) and port number (an integer) of a service. The entries are in the same order as returned by Avahi, but only include services whose network addresses can actually be resolved using Avahi. Note that this information may change over time, as new services are announced on the network or removed from it. An application will typically call **avahi::avail** from time to time to check whether new information is available and then retrieve the updated service list using...
avahi::get. The result may also be a negative integer (indicating the Avahi error code) in case of error.

3.6 Example

Here’s an example showing how to publish an UDP OSC (Open Sound Control) service which might be used to connect to mobile OSC applications such as hexler’s TouchOSC:

```cpp
using avahi;
using namespace avahi;

let s = publish "OSC Server" "._osc._udp" 8000;
check s;
```

The last line checks for the result of the operation and returns the actual service name, type and port number if all went well. A TouchOSC instance running on the local network will then offer you to connect to the service.

Continuing the example, here’s how you can obtain a list of OSC services currently available on your local network:

```cpp
let t = browse "._osc._udp";
avail t;
get t;
```

If you’re running TouchOSC somewhere on your local network, it will be listed there, along with our own service which we published above. The call in the second line can be used to check whether any new information is available. Applications typically invoke these two from time to time to update their service list, using code like the following:

```cpp
avail t && get t;
```
pure-bonjour: Pure Bonjour Interface

Version 0.2, April 11, 2018
Albert Gräf <aggraef@gmail.com>

This is a simple interface to Bonjour, Apple’s Zeroconf implementation. The module lets you publish and query Zeroconf network services using Bonjour, allowing you to establish connections for various kinds of TCP and UDP network services without having to manually configure network addresses. It is typically used along with the sockets module which lets you create the network connections discovered with bonjour.

To keep things simple and easy to use, the module only exposes the most essential functionality of Bonjour right now, but the provided functions should hopefully be sufficient for most programs which require interoperability with other Zeroconf applications. One known limitation is that the module allows you to publish and discover services in the default Bonjour domain only. Typically this is the local domain, limiting you to services in the local network. However, this should cover most common uses of Zeroconf.

There’s a companion avahi module which implements the same API for Avahi, the prevalent Zeroconf implementation on Linux systems. Since both modules implement the same functions, albeit in different namespaces, they can be used as drop-in replacements for each other. We also offer a compatibility module named zeroconf which can be used with either pure-avahi or pure-bonjour in a transparent fashion, so that no source changes are needed when switching the underlying implementation; please check the zeroconf.pure script included in the sources for details.

This module is in its early stages, so it may still contain bugs or lack some features. Please report bugs on the issue tracker at the Pure Bitbucket site, and use the Pure mailing list for general discussion of the module.

4.1 Copying

Copyright (c) 2014 by Albert Graef.
pure-bonjour is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-bonjour is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

4.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-bonjour-0.2.tar.gz.

Run make to compile the module and make install (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure and Bonjour installed. The latter should be readily available on most Linux systems, and ports are available for BSD systems as well.

make tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually, please check the Makefile for details.

Please note that the zeroconf.pure compatibility module is not installed by default, so you may want to copy it to the Pure library directory if needed.

4.3 Usage

To use the operations of this module, you need to have Bonjour (or a compatible Zeroconf implementation such as Avahi) installed and the corresponding service running on your system. If you have a Mac running OS X, then most likely Bonjour is already up and running, but for other systems you’ll have to consult your system documentation for instructions.

The following import declaration loads the functions of the bonjour module in your Pure script:

using bonjour;

All operations are in the bonjour namespace, so you might want to add the following declaration to access the functions using their unqualified identifiers:

using namespace bonjour;

4.4 Publishing Services

These functions allow you to advertise a network service using Bonjour, so that the service can be discovered by other applications participating in the Zeroconf protocol. Each service has a name (a string which uniquely identifies the service), a type (indicating the application
and transport protocols utilized by the service) and a port number (TCP or UDP port number, depending on the service type). The service type normally takes the form \_app\_tcp (for TCP services) or \_app\_udp (for UDP), where \_app specifies the protocol of the particular application (such as \_ipp for network-connected printers, or \_osc for applications speaking the OSC a.k.a. Open Sound Control protocol).

\texttt{bonjour::publish} name stype port

Advertise a service in the local domain, given by its name (a string), service type (a string) and (TCP or UDP) port number (an integer). Note that this operation is actually carried out asynchronously. Use \texttt{bonjour::check} below to wait for and report the result of the operation. The returned result is a pointer to the service object which can be passed to the following operations, or NULL in case of error. (A NULL pointer can be passed safely to \texttt{bonjour::check}; it will fail in this case.) The service will be unpublished automatically when the service object is garbage-collected.

\texttt{bonjour::check} service

Check for the result of a \texttt{bonjour::publish} operation. This blocks until a result is available. A negative integer value indicates failure (in this case the result is the Bonjour error code). Otherwise the result is a triple with the actual service name, type and port. Note that the name may be different from the one passed to \texttt{bonjour::publish} if there was a name collision with another service. Such collisions are usually resolved automatically by tacking on a suffix to the service name.

\section{4.5 Discovering Services}

These functions let you discover services of a given service type. For each (resolvable) service you’ll be able to retrieve the corresponding network address and port, which is what you’ll need to actually open a network connection to communicate with the service.

\texttt{bonjour::browse} stype

Browse available services of a given type in the local domain. This operation is carried out asynchronously; use \texttt{bonjour::avail} below to check whether new information is available, and \texttt{bonjour::get} to retrieve the actual service list. The result returned by \texttt{bonjour::browse} is a pointer to the browser object which can be passed to the following operations, or NULL in case of error. (A NULL pointer can be passed safely to the other operations; they will fail in this case.) Any resources allocated to the browser will be released automatically when the browser object is garbage-collected.

\texttt{bonjour::avail} browser

Check whether the service information was updated since the last invocation of \texttt{bonjour::get}. Returns an integer (truth value), which may also be negative (indicating the Bonjour error code) in case of error.

\texttt{bonjour::get} browser

Retrieve the current list of services. Each list entry is a tuple with the name, type, domain, IP address (all string values) and port number (an integer) of a service. The entries are in the same order as returned by Bonjour, but only include services whose network addresses can actually be resolved using Bonjour. Note that this information may change over time, as new services are announced on the network or removed.
from it. An application will typically call `bonjour::avail` from time to time to check whether new information is available and then retrieve the updated service list using `bonjour::get`. The result may also be a negative integer (indicating the Bonjour error code) in case of error.

### 4.6 Example

Here’s an example showing how to publish an UDP OSC (Open Sound Control) service which might be used to connect to mobile OSC applications such as hexler’s TouchOSC:

```cpp
using bonjour;
using namespace bonjour;

let s = publish "OSC Server" "_osc._udp" 8000;
check s;
```

The last line checks for the result of the operation and returns the actual service name, type and port number if all went well. A TouchOSC instance running on the local network will then offer you to connect to the service.

Continuing the example, here’s how you can obtain a list of OSC services currently available on your local network:

```cpp
let t = browse "_osc._udp"
avail t;
get t;
```

If you’re running TouchOSC somewhere on your local network, it will be listed there, along with our own service which we published above. The call in the second line can be used to check whether any new information is available. Applications typically invoke these two from time to time to update their service list, using code like the following:

```cpp
avail t && get t;
```
Chapter 5

pure-doc

Version 0.7, April 11, 2018

Albert Graef <aggraef@gmail.com>

pure-doc is a simple utility for literate programming and documenting source code written in the Pure programming language. It is designed to be used with the excellent docutils tools and the gentle markup format supported by these, called RST a.k.a. “reStructuredText”, usually pronounced “rest”.

The basic idea is that you just comment your code as usual, but using RST markup instead of plain text. In addition, you can also designate literate programming fragments in your code, which will be translated to RST literal blocks automatically. You then run pure-doc on your source files to extract all marked up comments and the literate code blocks. The resulting RST source can then be processed with the docutils utilities like rst2html.py and rst2latex.py to create the documentation in a variety of formats.

5.1 Copying

Copyright (c) 2009-2010 by Albert Graef.

pure-doc is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-doc is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.
### 5.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-doc-0.7.tar.gz.

Unpack and do the customary make && sudo make install. This only needs flex and a standards-compliant C++ compiler.

### 5.3 Usage

First, see the description of the RST format. RST is a very simple markup format, almost like plain text (in fact, you’re looking at RST right now, this document is written in it!). You can learn enough of it to start marking up your source in about five minutes.

Second, you’ll have to mark up your source comments. pure-doc recognizes comments in RST format by looking at the first non-empty line of the comment. A comment (either /* ... */ or a contiguous sequence of // line comments) is assumed to contain RST format if the first non-empty line starts with :,:), .. or ___. Other comments are taken to be plain text and are ignored by pure-doc.

Notes:

- pure-doc makes no other assumption about the contents of marked up comments, so you can include whatever you want: titles, section headers, fields, admonitions, plain text, whatever. Just make sure that the comment starts with one of the special tokens listed above. (You can always put just .. at the beginning of the comment to force it to be recognized, this will be treated as a comment by the docutils tools.)
- Also, pure-doc makes very few assumptions about the source; in fact, any source files with a C/C++-like comment and string syntax should work. So you could also use it to document your C/C++ programs, or even plain text files like this one, as long as they adhere to these standards.
- Indentation in extracted comments is preserved (assuming tabs = 8 spaces by default, you can change this with the -t option). This is important because indentation conveys document structure in RST.

For instance, here is a sample RST-formatted comment:

```rst
/* :Name: ''rand'' - compute random numbers
 :Synopsis: ''rand''
 :Description: Computes a (pseudo) random number. Takes no parameters.
 :Example: Here is how you can call ``rand`` in Pure:
 ::

    > extern int rand();
    > rand;
    1884289383

 :See Also: rand(3) */
```

This will be rendered as follows:
Name  rand - compute random numbers

Synopsis  rand

Description  Computes a (pseudo) random number. Takes no parameters.

Example  Here is how you can call rand in Pure:

```
> extern int rand();
> rand;
1804289383
```

See Also  rand(3)

Finally, to extract the documentation you run pure-doc on your source files as follows:

```
pure-doc source-files ...
```

If no input files are specified then the source is read from standard input. Otherwise all input files are read and processed in the indicated order. The output is written to stdout, so that you can directly pipe it into one of the docutils programs:

```
pure-doc source-files ... | rst2html.py
```

If you prefer to write the output to a file, you can do that as follows:

```
pure-doc source-files ... > rst-file
```

pure-doc also understands the following options. These must come before any file arguments.

- **h**  Print a short help message.

- **i**  Automatic index creation (see below).

- **s**  Generate Sphinx-compatible output (see below).

- **-twidth**  Set the tab width to the given number of spaces.

There are no other options. By its design pure-doc is just a plain simple “docstring scraping” utility with no formatting knowledge of its own. All actual formatting is handled by the docutils programs which offer plenty of options to change the appearance of the generated output; please refer to the docutils documentation for details.

Note that since Pure 0.46, all Pure documentation is usually formatted using Sphinx, the RST formatter used by the Python project which provides cross-document indexing and referencing, and even more elaborate formatting options and prettier output than docutils. pure-doc versions since 0.6 support this by adding the -s option which makes its output compatible with Sphinx. (At present this option actually has any effect only when combined with the -i index generation option, see Hyperlink Targets and Index Generation below.)
5.4 Literate Programming

pure-doc also recognizes literate code delimited by comments which, besides the comment delimiters and whitespace, contain nothing but the special start and end “tags” >>> and <<<. Code between these delimiters (including all comments) is extracted from the source and output as a RST literal code block.

For instance:
/* ..
   
   pure-doc supports literate programming, too. */

// >>>

// This is a literate comment.
/* .. This too! */

extern int rand();
rand;

// <<<

This will be rendered as follows:

pure-doc supports literate programming, too.

// This is a literate comment.
/* .. This too! */

extern int rand();
rand;

Try it now! You can scrape all the sample “documentation” from this file and format it as html, as follows:

`pure-doc README | rst2html.py --no-doc-title --no-doc-info > test.html`

5.5 Hyperlink Targets and Index Generation

**Note:** This feature is now largely obsolete as Pure uses Sphinx for formatting its documentation these days. Thus, as of version 0.6, the indexing feature must be enabled explicitly with the -i option.

When run with the -i option, pure-doc supplements the normal hyperlink target processing by the docutils tools, by recognizing explicit hyperlink targets of the form .. _target: and automatically creating raw html targets (<a name=...>) for them. This works around the docutils name mangling (which is undesirable if you’re indexing, say, function names). It also resolves a quirk with some w3m versions which don’t pick up all id attributes in the docutils-generated html source.
In addition, you can also have pure-doc generate an index from all explicit targets. To these ends, just add the following special directive at the place where you want the index to appear:

```
.. makeindex::
```

The directive will be replaced with a list of references to all targets collected up to that point, sorted alphabetically. This also resets the list of collected targets, so that you can have multiple smaller indices in your document instead of one big one.

It goes without saying that this facility is rather simplistic, but it may be useful when you are working with plain docutils which does not provide its own indexing facility. Note, however, that docutils doesn’t allow multiple explicit targets with the same name, so you should take that into consideration when devising your index terms.

Also note that in Sphinx compatibility mode (-s), pure-doc will generate the appropriate Sphinx markup for index entries (index::) instead, and the makeindex:: directive will be ignored. You should then use Sphinx to generate the index.

Finally, if the -i option isn’t specified, then all this special processing is disabled and the makeindex:: directive won’t be recognized at all. This is the recommended way to process Pure documentation files which have been fully converted to Sphinx.

### 5.6 Generating and Installing Local Documentation

**Note:** This section only applies to 3rd party packages with their own bundled documentation which isn’t part of the “official” Pure documentation. In this case it is possible to use docutils or some other RST formatting software to generate additional documentation files for use with the Pure interpreter. Please note that the method sketched out in this section doesn’t provide full integration with the rest of Pure’s documentation, but at least it makes it possible to read the local documentation in the interpreter.

If you’re generating some library documentation for which you have to process a bigger collection of source files, then it is often convenient to have a few Makefile rules to automatize the process. To these ends, simply add rules similar to the following to your Makefile (the following assumes GNU make and that you’re using docutils to format the documentation):

```
# The sources. Order matters here. The generated documentation will have the
# comments from each source file in the indicated order.
sources = foo.pure bar.pure

# The basename of the documentation files to be generated.
target = foo

.PHONY: html tex pdf

html: $(target).html
tex: $(target).tex
pdf: $(target).pdf
```
$(target).txt: $(sources)
   pure-doc $(sources) > @$

# This requires that you have docutils installed.
%.html: %.txt
   rst2html.py $< $@

%.tex: %.txt
   rst2latex.py $< $@

# This also requires that you have TeX installed.
%.pdf: %.tex
   pdflatex $<
   rm -f *.aux *.log *.out

clean:
   rm -f *.html *.tex *.pdf

You might want to add -i to the pure-doc command line if you want to enable the indexing feature described in the previous section. If you want to use some other RST formatting software, please check the corresponding documentation for information on how to format your documents and adjust the above rules for the html, tex and pdf targets accordingly.

Now you can just type make html to generate the documentation in html format, and make tex or make pdf to generate the other formats. The clean target removes the generated files.

Having generated the documentation files in html format, you can install them in the docs subdirectory of the Pure library directory to make it known to the Pure interpreter, so that you can read your documentation with the help command of the interpreter. (When doing this, name your documentation files in such a manner that you don’t overwrite any of the Pure documentation files there.) The following Makefile rule automatizes this process. Add this to the Makefile in the previous section:

# Try to guess the installation prefix (this needs GNU make):
prefix = $(patsubst %/bin/pure,%,$(shell which pure 2>/dev/null))
ifeq ($(strip $(prefix)),)
   # Fall back to /usr/local.
   prefix = /usr/local
endif

libdir = $(prefix)/lib
docsdir = $(libdir)/pure/docs

install:
   test -d "$(DESTDIR)$(docsdir)" || mkdir -p "$(DESTDIR)$(docsdir)"
   cp $(target).html "$(DESTDIR)$(docsdir)"

After a make install your documentation should now end up in the appropriate place in the Pure library directory and you can read it in the Pure interpreter using a command like
Note the hash character. This tells the help command that this is an auxiliary documentation file, rather than a search term to be looked up in the Pure documentation. You can also look up a specific section in your manual as follows:

> help foo#section-name

Please also refer to The Pure Manual for more information on how to use the interpreter’s online help.

5.7 Formatting Tips

If you’re generating documentation in pdf format using plain docutils, you might have to fiddle with the formatting to get results suitable for publication purposes. Newer versions of the rts2latex.py program provide some options which let you adjust the formatting of various document elements. Here are the options that the author found particularly helpful:

- The table of contents that RST produces isn’t all that useful in printed documentation, since it lacks page numbers. As a remedy, you can invoke rst2latex with --use-latex-toc to have LaTeX handle the formatting of the table of contents, which looks much nicer.

- Similarly, --use-latex-docinfo can be used to tell rst2latex that you want the title information (author and date) to be formatted the LaTeX way.

- If you need specific LaTeX document options, these can be specified with --documentoptions, e.g.: --documentoptions="11pt".

- For more comprehensive formatting changes which require special LaTeX code and/or packages, you can use the --stylesheet option. E.g., --stylesheet=preamble.tex will cause a preamble.tex file with your own definitions to be included in the preamble of the generated document.

- To format literal code blocks using an alternative environment instead of the default verbatim environment, use the --literal-block-env option. E.g., --literal-block-env=lstlisting will use the highlighted code environment from the listings package. (Note that in this case you’ll also need a preamble which loads the corresponding package.)

To learn more about this, please consult the rts2latex.py documentation at the docutils website.

In addition, the pure-doc package contains a little GNU awk script called fixdoc, which attempts to improve the LaTeX output produced by older svn versions of rst2latex in various ways. (This isn’t necessary for the latest rst2latex versions, or if you use Sphinx.)
The libffi library provides a portable, high level programming interface to various calling conventions. This allows a programmer to call any function specified by a call interface description at run time. libffi should be present on most gcc-based systems, but it is also available as a standalone package at http://sourceware.org/libffi/.

This module provides an interface to libffi which enables you to call C functions from Pure and vice versa. It goes beyond Pure’s built-in C interface in that it also handles C structs and makes Pure functions callable from C. Moreover, depending on the libffi implementation, it may also be possible to call foreign languages other than C.

6.1 Copying

Copyright (c) 2008, 2009 by Albert Graef.

pure-ffi is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-ffi is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

6.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-ffi-0.16.tar.gz.
Run `make` to compile the module and `make install` (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure and libffi installed.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, `make install prefix=/usr` sets the installation prefix, and `make PIC=-fPIC` or some similar flag might be needed for compilation on 64 bit systems. Please see the Makefile for details.

NOTE: This module requires libffi 3.x (3.0.8 has been tested). Old libffi versions (2.x) do not appear to work (closures are broken). Patches are welcome.

6.3 Usage

The module exposes a simplified interface to libffi tailored to the Pure language. Call interfaces are described using the desired ABI, return type and tuple of argument types. The ABI is specified using one of the `FFI_*` constants defined by the module; for most purposes, `FFI_DEFAULT_ABI` is all that’s needed. C types are specified using special descriptors `void_t`, `uint_t` etc., see ffi.pure for details. You can also get a list of these values using `show -g FFI_* _t` after importing the ffi module.

The primary interface for calling C from Pure and vice versa is as follows:

```makefile
fcall name abi rtype atypes
```

Creates a Pure function from a C function with the given name, specified as a string. This makes the C function callable in Pure, no matter whether it is already declared as an `extern` or not. But note that if the function resides in a shared library, you still have to import that library using a Pure `using` declaration, see the Pure manual for details.

```makefile
fclos fn abi rtype atypes
```

Creates a pointer to a C function from the given Pure function `fn`. The resulting pointer can then be passed to other C functions expecting functions as arguments. This allows you to create C callbacks from Pure functions without writing a single line of C code. (This functionality might not be available on some platforms.)

Note that in difference to `extern` functions, arguments to functions created with libffi are always passed in uncurried form, as a Pure tuple. E.g.:

```makefile
> using ffi;
> let fmod = fcall "fmod" FFI_DEFAULT_ABI double_t (double_t,double_t);
> fmod (5.3,0.7);
0.4
```

C structs are fully supported and are passed in a type-safe manner, see ffi.pure for details. Note that these are to be used for passing structs by value. (When passing a pointer to a struct, you must use `pointer_t` instead.) For instance:

```makefile
> let complex_t = struct_t (double_t,double_t);
> let cexp = fcall "cexp" FFI_DEFAULT_ABI complex_t (complex_t);
> members (cexp (struct complex_t (0.0,1.0)));
0.54030230586814,0.841470984807897
```
See the examples folder in the sources for more examples.

6.4 TODO

The API isn’t perfect yet. In particular, one might consider to implement type descriptors as structs instead of raw pointers, and support for typed pointers would be useful. Contributions and suggestions are welcome.
7.1 Name

pure-gen – Pure interface generator

pure-gen is a C interface generator for the Pure language. It takes a C header file as input and generates a corresponding Pure module with the constant definitions and extern declarations needed to use the C module from Pure. pure-gen can also generate FFI interfaces rather than externs (using the pure-ffi module), and it can optionally create a C wrapper module which allows you to create interfaces to pretty much any code which can be called via C.

7.2 Synopsis

pure-gen [options ...] input-file

7.3 Options

7.3.1 General Options

-h
   --help
       Print a brief help message and exit.

-V
   --version
       Print version number and exit.
-e
--echo
    Echo preprocessor lines. Prints all processed #defines, useful for debugging purposes.

-v
--verbose
    Show parameters and progress information. Gives useful information about the conversion process.

-w[level]
--warnings[level]
    Display warnings, level = 0 (disable most warnings), 1 (default, shows important warnings only) or 2 (lots of additional warnings useful for debugging purposes).

7.3.2 Preprocessor Options

-I path
--include path
    Add include path. Passed to the C preprocessor.

-D name[=value]
--define name[=value]
    Define symbol. Passed to the C preprocessor.

-U name
--undefine name
    Undefine symbol. Passed to the C preprocessor.

-C option
--cpp option
    Pass through other preprocessor options and arguments.

7.3.3 Generator Options

-f iface
--interface iface
    Interface type (extern, c, ffi or c-ffi). Default is extern. The extern and c types generate Pure extern declarations, which is what you want in most cases. ffi and c-ffi employ Pure’s libffi interface instead. The c and c-ffi types cause an additional C wrapper module to be created (see Generating C Code). These can also be combined with the -auto suffix which creates C wrappers only when needed to get C struct arguments and returns working, see Dealing with C Structs for details.

-l lib
--lib-name lib
    Add dynamic library module to be imported in the Pure output file. Default is -l c-file (the filename specified with -c, see below, without filename extension) if one of the -fc options was specified, none otherwise.

-m name
--namespace name
Module namespace in which symbols should be declared.

-p prefix
--prefix prefix
Module name prefix to be removed from C symbols.

-P prefix
--wrap prefix
Prefix to be prepended to C wrapper symbols (\(-fc\) and friends). Default is Pure_.

-a
--all
Include “hidden” symbols in the output. Built-in preprocessor symbols and symbols starting with an underscore are excluded unless this option is specified.

-s pattern
--select pattern
Selection of C symbols to be included in the output. pattern takes the form [glob-patterns::][regex-pattern], designating a comma separated list of glob patterns matching the source filenames, and an extended regular expression matching the symbols to be processed. See glob(7) and regex(7). The default pattern is empty which matches all symbols in all source modules.

-x pattern
--exclude pattern
Like -s, but excludes all matching C symbols from the selection.

-t file
--template file
Specify a C template file to be used with C wrapper generation (\(-fc\)). See Generating C Code for details.

-T file
--alt-template file
Specify an alternate C template file to be used with C wrapper generation (\(-fc\)). See Generating C Code for details.

7.3.4 Output Options

-n
--dry-run
Only parse without generating any output.

-N
--noclobber
Append output to existing files.

-o file
--output file
Pure output (.pure) filename. Default is input-file with new extension .pure.
-c file
--c-output file
    C wrapper (.c) filename (-fc). Default is input-file with new extension .c.

7.4 Description

pure-gen generates Pure bindings for C functions from a C header file. For instance, the command

```
pure-gen foo.h
```

creates a Pure module foo.pure with extern declarations for the constants (defines and enums) and C routines declared in the given C header file and (recursively) its includes.

pure-gen only accepts a single header file on the command line. If you need to parse more than one header in a single run, you can just create a dummy header with all the necessary #includes in it and pass that to pure-gen instead.

When invoked with the -n option, pure-gen performs a dry run in which it only parses the input without actually generating any output files. This is useful for checking the input (possibly in combination with the -e, -v and/or -w options) before generating output. A particularly useful example is

```
pure-gen -ne foo.h \
  | awk 's1=="#" && $2~/^[0-9]+$/ && $3!~/^"<.*">$/ { print $3 }' \
  | sort | uniq
```

which prints on standard output all headers which are included in the source. This helps to decide which headers you want to be included in the output, so that you can set up a corresponding filter patterns (-s and -x options, see below).

The -I, -D and -U options are simply passed to the C preprocessor, as well as any other option or argument escaped with the -C flag. This is handy if you need to define additional preprocessor symbols, add directories to the include search path, etc., see cpp(1) for details.

There are some other options which affect the generated output. In particular, -f c generates a C wrapper module along with the Pure module (see Generating C Code below), and -f ffi generates a wrapper using Pure’s ffi module. Moreover, -l libfoo generates a using "lib:libfoo" declaration in the Pure source, for modules which require a shared library to be loaded. Any number of -l options can be specified.

Other options for more advanced uses are explained in the following sections.

7.5 Filtering

Note that pure-gen always parses the given header file as well as all its includes. If the header file includes system headers, by default you will get those declarations as well. This is often undesirable. As a remedy, pure-gen normally excludes built-in defines of the C
preprocessor, as well as identifiers with a leading underscore (which are often found in system headers) from processing. You can use the -a option to disable this, so that all these symbols are included as well.

In addition, the -s and -x options enable you to filter C symbols using the source filename and the symbol as search criteria. For instance, to just generate code for a single header foo.h and none of the other headers included in foo.h, you can invoke pure-gen as follows:

```
pure-gen -s foo.h:: foo.h
```

Note that even in this case all included headers will be parsed so that #defined constants and enum values can be resolved, but the generated output will only contain definitions and declarations from the given header file.

In general, the -s option takes an argument of the form glob-patterns:regex-pattern denoting a comma-separated list of glob patterns to be matched against the source filename in which the symbol resides, and an extended regex to be matched against the symbol itself. The glob-patterns:: part can also be omitted in which case it defaults to :: which matches any source file. The regex can also be empty, in which case it matches any symbol. The generated output will contain only the constant and function symbols matching the given regex, from source files matching any of the the glob patterns. Thus, for instance, the option

```
-s foo.h,bar.h::^(foo|bar)_ pulls all symbols prefixed with either foo or bar from the files foo.h and bar.h in the current directory.
```

Instead of :: you can also use a single semicolon ; to separate glob and regex pattern. This is mainly for Windows compatibility, where the msys shell sometimes eats the colons or changes them to ;.

The -x option works exactly the same, but excludes all matching symbols from the selection. Thus, e.g., the option -x ^bar_ causes all symbols with the prefix bar_ to not be included in the output module.

Processing of glob patterns is performed using the customary rules for filename matching, see glob(7) for details. Note that some include files may be specified using a full pathname. This is the case, in particular, for system includes such as #include <stdio.h>, which are resolved by the C preprocessor employing a search of the system include directories (as well as any directories named with the -I option).

Since the * and ? wildcards never match the pathname separator /, you have to specify the path in the glob patterns in such cases. Thus, e.g., if the foo.h file actually lives in either /usr/include or /usr/local/include, then it must be matched using a pattern like /usr/include/*.*:/usr/local/include/*:: . Just foo.h:: will not work in this case. On the other hand, if you have set up your C sources in some local directory then specifying a relative pathname is ok.

### 7.6 Name Mangling

The -s option is often used in conjunction with the -p option, which lets you specify a “module name prefix” which should be stripped off from C symbols. Case is insignificant and a trailing underscore will be removed as well, so -p foo turns fooBar into Bar and
F00..BAR into BAR. Moreover, the \texttt{-m} option allows you to specify the name of a Pure name-space in which the resulting constants and functions are to be declared. So, for instance, 
\texttt{-s "\(^{-(foo|F00)}\)" -p foo -m foo} will select all symbols starting with the \texttt{foo} or \texttt{F00} prefix, stripping the prefix from the selected symbols and finally adding a \texttt{foo::} namespace qualifier to them instead.

\section*{7.7 Generating C Code}

As already mentioned, pure-gen can be invoked with the \texttt{-fc} or \texttt{-fc-ffi} option to create a C wrapper module along with the Pure module it generates. There are various situations in which this is preferable, e.g.:

- You are about to create a new module for which you want to generate some boilerplate code.
- The C routines to be wrapped aren't available in a shared library, but in some other form (e.g., object file or static library).
- You need to inject some custom code into the wrapper functions (e.g., to implement custom argument preprocessing or lazy dynamic loading of functions from a shared library).
- The C routines can't be called directly through Pure externs.

The latter case might arise, e.g., if the module uses non-C linkage or calling conventions, or if some of the operations to be wrapped are actually implemented as C macros. (Note that in order to wrap macros as functions you'll have to create a staged header which declares the macros as C functions, so that they are wrapped in the C module. pure-gen doesn't do this automatically.)

Another important case is that some of the C routines pass C structs by value or return them as results. This is discussed in more detail in the following section.

For instance, let's say that we want to generate a wrapper foo.c from the foo.h header file whose operations are implemented in some library libfoo.a or libfoo.so. A command like the following generates both the C wrapper and the corresponding Pure module:

\begin{verbatim}
pure-gen -fc foo.h
\end{verbatim}

This creates foo.pure and foo.c, with an import clause for "\texttt{lib:foo}" at the beginning of the Pure module. (You can also change the name of the Pure and C output files using the \texttt{-o} and \texttt{-c} options, respectively.)

The generated wrapper is just an ordinary C file which should be compiled to a shared object (dll on Windows) as usual. E.g., using gcc on Linux:

\begin{verbatim}
gcc -shared -o foo.so foo.c -lfoo
\end{verbatim}

That's all. You should now be able to use the foo module by just putting the declaration using foo; into your programs. The same approach also works with the ffi interface if you replace the \texttt{-fc} option with \texttt{-fc-ffi}.
You can also adjust the C wrapper code to some extent by providing your own template file, which has the following format:

```c
/* frontmatter here */
#include %h
%

/* wrapper here */
%r %w(%p)
{
    return %n(%a);
}
```

Note that the code up to the symbol `%` on a line by itself denotes “frontmatter” which gets inserted at the beginning of the C file. (The frontmatter section can also be empty or missing altogether if you don’t need it, but usually it will contain at least an `#include` for the input header file.)

The rest of the template is the code for each wrapper function. Substitutions of various syntactical fragments of the function definition is performed using the following placeholders:

- `%h` input header file
- `%r` return type of the function
- `%w` the name of the wrapper function
- `%p` declaration of the formal parameters of the wrapper function
- `%n` the real function name (i.e., the name of the target C function to be called)
- `%a` the arguments of the function call (formal parameters with types stripped off)
- `%` escapes a literal `%`

A default template is provided if you don’t specify one (which looks pretty much like the template above, minus the comments). A custom template is specified with the `-t` option. (There’s also a `-T` option to specify an “alternate” template for dealing with routines returning struct values, see Dealing with C Structs.)

For instance, suppose that we place the sample template above into a file `foo.templ` and invoke `pure-gen` on the `foo.h` header file as follows:

```
pure-gen -fc -t foo.templ foo.h
```

Then in `foo.c` you’d get C output code like the following:

```c
/* frontmatter here */
#include "foo.h"

/* wrapper here */
void Pure_foo(int arg0, void* arg1)
{
    return foo(arg0, arg1);
}
```
As indicated, the wrapper function names are usually stropped with the Pure_ prefix. You can change this with the -P option.

This also works great to create boilerplate code for new modules. For this purpose the following template will do the trick:

```c
/* Add #includes etc. here. */

%r %n(%p)
{
  /* Enter code of %n here. */
}
```

### 7.8 Dealing with C Structs

Modern C compilers allow you to pass C structs by value or return them as results from a C function. This represents a problem, because Pure doesn’t provide any support for that in its extern declarations. Even Pure’s libffi interface only has limited support for C structs (no unions, no bit fields), and at present pure-gen itself does not keep track of the internal structure of C structs either.

Hence pure-gen will bark if you try to wrap an operation which passes or returns a C struct, printing a warning message like the following which indicates that the given function could not be wrapped:

```
Warning: foo: struct argument or return type, try -fc-auto
```

What Pure does know is how to pass and return pointers to C structs in its C interface. This makes it possible to deal with struct arguments and return values in the C wrapper. To make this work, you need to create a C wrapper module as explained in the previous section. However, as C wrappers are only needed for functions which actually have struct arguments or return values, you can also use the -fc-auto option (or -fc-ffi-auto if you prefer the ffi interface) to only generate the C wrapper when required. This saves the overhead of an extra function call if it’s not actually needed.

Struct arguments in the original C function then become struct pointers in the wrapper function. E.g., if the function is declared in the header as follows:

```c
typedef struct {
  double x, y;
} point;
extern double foo(point p);
```

Then the generated wrapper code becomes:
double Pure_foo(point* arg0)
{
    return foo(*arg0);
}

Which is declared in the Pure interface as:

extern double Pure_foo(point*) = foo;

Struct return values are handled by returning a pointer to a static variable holding the return value. E.g.,

extern point bar(double x, double y);

becomes:

point* Pure_bar(double arg0, double arg1)
{
    static point ret;
    ret = bar(arg0, arg1); return &ret;
}

Which is declared in the Pure interface as:

extern point* Pure_bar(double, double) = bar;

(Note that the generated code in this case comes from an alternate template. It's possible to configure the alternate template just like the normal one, using the -T option instead of -t. See the Generating C Code section above for details about code templates.)

In a Pure script you can now call foo and bar as:

> foo (bar 0.0 1.0);

Note, however, that the pointer returned by bar points to static storage which will be overwritten each time you invoke the bar function. Thus in the following example both u and v will point to the same point struct, namely that defined by the latter call to bar:

> let u = bar 1.0 0.0; let v = bar 0.0 1.0;

Which most likely is not what you want. To avoid this, you’ll have to take dynamic copies of returned structs. It’s possible to do this manually by fiddling around with malloc and memcpy, but the most convenient way is to employ the struct functions provided by Pure’s ffi module:

> using ffi;
> let point_t = struct_t (double_t, double_t);
> let u = copy_struct point_t (bar 1.0 0.0);
> let v = copy_struct point_t (bar 0.0 1.0);

Now u and v point to different, malloc’d structs which even take care of freeing themselves when they are no longer needed. Moreover, the ffi module also allows you to access the
members of the structs in a direct fashion. Please refer to the pure-ffi documentation for further details.

7.9 Notes

pure-gen currently requires gcc (-E) as the C preprocessor. It also needs a version of gcc which understands the -fdirectives-only option, which means gcc 4.3 or later. It will run with older versions of gcc, but then you'll get an error message from gcc indicating that it doesn't understand the -fdirectives-only option. pure-gen then won't be able to extract any #defined constants from the header files.

pure-gen itself is written in Pure, but uses a C parser implemented in Haskell, based on the Language.C library written by Manuel Chakravarty and others.

pure-gen can only generate C bindings at this time. Other languages may have their own calling conventions which make it hard or even impossible to call them directly through Pure’s extern interface. However, if your C compiler knows how to call the other language, then it may be possible to interface to modules written in that language by faking a C header for the module and generating a C wrapper with a custom code template, as described in Generating C Code. In principle, this approach should even work with behemoths like C++, although it might be easier to use third-party tools like SWIG for that purpose.

In difference to SWIG and similar tools, pure-gen doesn't require you to write any special “interface files”, is controlled entirely by command line options, and the amount of marshalling overhead in C wrappers is negligible. This is possible since pure-gen targets only the Pure-C interface and Pure has good support for interfacing to C built into the language already.

pure-gen usually works pretty well if the processed header files are written in a fairly clean fashion. Nevertheless, some libraries defy fully automatic wrapper generation and may thus require staged headers and/or manual editing of the generated output to get a nice wrapper module.

In complex cases it may also be necessary to assemble the output of several runs of pure-gen for different combinations of header files, symbol selections and/or namespace/prefix settings. In such a situation it is usually possible to just concatenate the various output files produced by pure-gen to consolidate them into a single wrapper module. To make this easier, pure-gen provides the -N a.k.a. --noclobber option which appends the output to existing files instead of overwriting them. See the example below.

7.10 Example

For the sake of a substantial, real-world example, here is how you can wrap the entire GNU Scientific Library in a single Pure module mygsl.pure, with the accompanying C module in mygsl.c:

```bash
rm -f mygsl.pure mygsl.c
DEFS=-DGSL_DISABLE_DEPRECATED
for x in /usr/include/gsl/gsl_*.h; do
```

pure-gen $DEFS -N -fc-auto -s "$x::" $x -o mygsl.pure -c mygsl.c

The C module can then be compiled with:

gcc $DEFS -shared -o mygsl.so mygsl.c -lgsl

Note that the GSL_DISABLE_DEPRECATED symbol must be defined here to avoid some botches with constants being defined in incompatible ways in different GSL headers. Also, some GSL versions have broken headers lacking some system includes which causes hiccups in pure-gen's C parser. Fixing those errors or working around them through some appropriate \( \text{cpp} \) options should be a piece of cake, though.

7.11 License

BSD-like. See the accompanying COPYING file for details.

pure-readline

Version 0.3, April 11, 2018

Albert Graef <aggraef@gmail.com>

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-readline-0.3.tar.gz.

This is a trivial wrapper around GNU readline, which gives Pure scripts access to the most important facilities of the readline interface. This includes support for the `readline` function itself (without custom completion at present) and basic history management. The wrapper can also be used with the BSD editline a.k.a. libedit library, a readline replacement licensed under the 3-clause BSD license. You can find these at:

- GNU readline: http://tiswww.tis.case.edu/~chet/readline/rltop.html
- BSD editline/libedit: http://www.thrysoee.dk/editline

We recommend GNU readline because it’s easier to use and has full UTF-8 support, but in some situations BSD editline/libedit may be preferable for license reasons or because it’s what the operating system provides. Note that in either case Pure programs using this module are subject to the license terms of the library that you use (GPLv3+ in case of GNU readline, BSD license in the case of BSD editline/libedit).

Normally, you should choose the same library that you use with the Pure interpreter, to avoid having two different versions of the library linked into your program. (This doesn’t matter if you only use this module with batch-compiled scripts, though, since the Pure runtime doesn’t depend on readline in any way.) By default, the module will be built with GNU readline. To select editline/libedit instead, you only have to uncomment a line at the beginning of the Makefile. Also, you might want to check the beginning of readline.c for the proper location of the corresponding header files.

The module provides the following functions:

`readline` prompt

Read a line of input from the user, with prompting and command line editing. Returns
the input line (with the trailing newline removed), or NULL when reaching end of file.

**add_history** line
Add the given line (a string) to the command history.

**clear_history**
Clears the command history.

**read_history** fname
Reads the command history from the given file. Note that this in fact *adds* the contents of the history file to the current history, so you may want to call **clear_history** beforehand if this function is called multiple times.

**write_history** fname
Writes the current command history to the given file.

Example:

```plaintext
> using readline;
> readline "input> ";
input> Hello, world!
"Hello, world!"
> add_history ans;
()  
> readline "input> ";
input> <EOF>
#<pointer 0x0>
> write_history "history"; // save the history
0
> clear_history;
> read_history "history"; // read the history
0
```
Chapter 9

pure-sockets: Pure Sockets Interface

Version 0.8, April 11, 2018
Albert Gräf <aggraef@gmail.com>

This is an interface to the Berkeley socket functions. It provides most of the core functionality, so you can create sockets for both stream and datagram based protocols and use these to transmit messages. Unix-style file sockets are also available if the host system supports them.

9.1 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-sockets-0.8.tar.gz.

Run `make` to compile the module and `sudo make install` to install it in the Pure library directory. To uninstall the module, use `sudo make uninstall`. There are a number of other targets (mostly for maintainers), please see the Makefile for details.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, `make install prefix=/usr` sets the installation prefix, and `make PIC=-fPIC` or some similar flag might be needed for compilation on 64 bit systems. You can also set custom compilation options with the `CFLAGS` variable, e.g.: `make CFLAGS=-O3`. Again, please see the Makefile for details.

9.2 Usage

To use the operations of this module, put the following in your Pure script:

```
using sockets;
```

With the `sockets` module loaded, all the standard socket functions are available and work pretty much like in C. The only real difference is that, for convenience, functions taking
socket addresses as parameters (struct_sockaddr* pointers in Pure), are called without the addrlen parameter; the size of the socket address structure will be inferred automatically and passed to the underlying C functions. Also, there are some convenience functions which act as wrappers around getaddrinfo and getnameinfo to create socket addresses from symbolic information (hostname or ip, port names or numbers) and return information about existing address pointers, see Creating and Inspecting Socket Addresses below.

Below is a list of the provided functions. Please see the corresponding manual pages for details, and check the Pure scripts in the examples subdirectory for some examples.

### 9.2.1 Creating and Inspecting Socket Addresses

These functions are Pure-specific. The created socket addresses are malloc’ed and free themselves automatically when garbage-collected.

**sockaddr ()**
Create a pointer to an empty socket address suitable to hold the socket address result of routines like `accept`, `getsockname`, `recvfrom`, etc. which return a socket address.

**sockaddr ([int family,] char *path)**
Create a local (a.k.a. file) socket address for the given pathname. The family parameter, if specified, must be AF_UNIX here. Please note that AF_UNIX is not supported on all platforms. You can check for this by testing the HAVE_AF_UNIX constant, which is a truth value specifying whether AF_UNIX is available on your system.

**sockaddr ([int family,] char *host, char *port)**
**sockaddr ([int family,] char *host, int port)**
This uses getaddrinfo to retrieve an AF_INET or AF_INET6 address for the given hostname (or numeric IP address in string form) and port (specified either as an int or a string). If family is omitted, it defaults to AF_UNSPEC which matches both AF_INET and AF_INET6 addresses.

**sockaddrs ([int family,] char *host, char *port)**
**sockaddrs ([int family,] char *host, int port)**
This works like `sockaddr` above, but returns a list with all matching addresses.

**sockaddr_family addr**
Returns the address family of the given address.

**sockaddr_path addr**
Returns the pathname for AF_UNIX addresses.

**sockaddr_hostname addr**
Returns the hostname if available, the IP address otherwise.

**sockaddr_ip addr**
Returns the IP address.

**sockaddr_service addr**
Returns the service (a.k.a. port) name.
sockaddr_port `addr`
    Returns the port number.

sockaddr_info `addr`
    Returns a readable description of a socket address, as a `(family, hostname, port)` tuple. You should be able to pass this into sockaddr again to get the original address.

### 9.2.2 Creating and Closing Sockets

socket domain type protocol
    Creates a socket for the given protocol family (AF_UNIX, AF_INET or AF_INET6), socket type (SOCK_STREAM, SOCK_DGRAM, etc.) and protocol. Note that on Linux we also support the SOCK_NONBLOCK (non-blocking) and SOCK_CLOEXEC (close-on-exec) flags which can be or’ed with the socket type to get sockets with the corresponding features. The protocol number is usually 0, denoting the default protocol, but it can also be any of the prescribed IPPROTO constants (a few common ones are predefined by this module, try `show -g IPPROTO_*` for a list of those).

socketpair domain type protocol sv
    Create a pair of sockets. The descriptors are returned in the integer vector sv passed in the last argument.

shutdown fd how
    Perform shutdown on a socket. The second argument should be one of SHUT_RD, SHUT_WR and SHUT_RDWR.

closesocket fd
    This is provided for Windows compatibility. On POSIX systems this is just close.

### 9.2.3 Establishing Connections

accept sockfd addr
bind sockfd addr
connect sockfd addr
listen sockfd backlog

### 9.2.4 Socket I/O

recv fd buf len flags
send fd buf len flags
recvfrom fd buf len flags addr
sendto fd buf len flags addr

The usual send/recv flags specified by POSIX (MSG_EOR, MSG_OOB, MSG_PEEK, MSG_WAITALL) are provided. On Linux we also support MSG_DONTWAIT. Note that on POSIX systems you can also just `fdopen` the socket descriptor and use the standard file I/O operations from the `system` module instead.
9.2.5 Socket Information

getsockname fd addr
getpeername fd addr
getsockopt fd level name val len
setsockopt fd level name val len

For getsockopt and setsockopt, currently only the SOL_SOCKET level is defined (level argument) along with the available POSIX socket options (name argument). Try show -g SO_* to get a list of those. Also note that for most socket level options the val argument is actually an int*, so you can pass a Pure int vector (with len = SIZEOF_INT) for that parameter.

9.3 Example

Here is a fairly minimal example using Unix stream sockets. To keep things simple, this does no error checking whatsoever and just keeps sending strings back and forth. More elaborate examples can be found in the examples directory in the sources.

```
using sockets, system;

const path = "server_socket";
extern int unlink(char *name);

server = loop with
  loop = loop if ~null s && ~response fp s when
    // Connect to a client.
    cfd = accept fd $ sockaddr ();
    // Open the client socket as a FILE* and read a request.
    fp = fdopen cfd "r+"; s = fgets fp;
  end;
  loop = puts "server is exiting" $$ closesocket fd $$
    unlink path $$ () otherwise;
  response fp s::string = s=="quit\n" when
    // Process the request. (Here we just print the received
    // message and echo it back to the client.)
    printf "server> %s" s;
    fputs s fp;
  end;
end when
  // Create the server socket and start listening.
  unlink path;
  fd = socket AF_UNIX SOCK_STREAM 0;
  bind fd (sockaddr path); listen fd 5;
  printf "server listening at '%s'\n" path;
end;

client = loop with
  // Keep reading requests from stdin.
  loop = loop if ~null s && ~request s when
```
fputs "client> " stdout; s = fgets stdin;
end;
loop = puts "client is exiting" $$ () otherwise;
request s::string = s=="quit\n" when
  fd = socket AF_UNIX SOCK_STREAM 0;
  connect fd (sockaddr path);
  // Send the request to the server.
  fp = fdopen fd "r+"; fputs s fp;
  // Get the reply.
  s = fgets fp;
end;
end;

To use this example, run the server function in one instance of the Pure interpreter and the
client function in another. Enter a line when the client prompts you for input; it will be
printed by the server. Behind the scenes, the server also sends the line back to the client.
After receiving the reply, the client prompts for the next input line. Entering end-of-file at
the client prompt terminates the client but keeps the server running, so that you can start
another client and reconnect to the server. Entering just quit in the client terminates both
server and client. Here is how a typical interaction may look like:

> client;
client> 1+1
client> foo bar
client> quit
client is exiting
()

> server;
server listening at 'server_socket'
server> 1+1
server> foo bar
server> quit
server is exiting
()

Note that while the server processes requests sequentially, it accepts connections from a new
client after each request, so that you can run as many clients as you like.
Chapter 10

pure-stldict

Version 0.8, April 11, 2018
Albert Graef <aggraef@gmail.com>

This package provides a light-weight, no frills interface to the C++ dictionary containers \texttt{map} and \texttt{unordered\_map}. The \texttt{stldict} module makes these data structures available in Pure land and equips them with a (more or less) idiomatic Pure container interface.

The C++ containers are part of the standard C++ library, see the \texttt{C++ standard library documentation} for details. They were originally based on the Standard Template Library, so they are also sometimes referred to as “STL containers”; hence the name of this package.

10.1 Copying

Copyright (c) 2011 by Albert Graef.

pure-stldict is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-stldict is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

10.2 Installation

Get the latest source from \url{https://bitbucket.org/purelang/pure-lang/downloads/pure-stldict-0.8.tar.gz}. 379
Run `make` to compile the modules and `make install` (as root) to install them in the Pure library directory. This requires GNU make, and of course you need to have Pure (and a C++ library which includes the STL) installed.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually, please check the Makefile for details.

**Note:** This module requires Pure 0.50 or later and a recent version of the C++ library (GNU libstdc++ v3 has been tested). All proper C++11 libraries should work out of the box, while (recent) C++0x implementations may require some fiddling with the sources and/or the compilation options. Pre C++0x library versions surely require considerably more work, especially in the hashdict module.

## 10.3 Usage

After installation, you can use the operations of this package by placing the following import declaration in your Pure programs:

```pure
using stldict;
```

This imports the whole shebang. If you only need either the hashed or the ordered dictionaries, you can also import the corresponding modules separately, i.e.:

```pure
using hashdict;
```

or:

```pure
using orddict;
```

## 10.4 Types

In Pure land, the C++ map and unordered_map containers and their multimap variants are made available as a collection of four data structures:

**type hashdict**

**type hashmdict**

Hashed (unordered) dictionary data structures. These work with arbitrary key (and value) types, like the hashed dictionary and set data structures in the standard library, and can be found in the `hashdict.pure` module.

**type orddict**

**type orddict**

Ordered dictionary data structures. These require the keys to be ordered by the standard `<` predicate, like the ordered dictionary and set data structures in the standard library, and can be found in the `orddict.pure` module.

Note that `hashdict` and `hashmdict` differ in that the former has exactly one key-value association for each key in the dictionary, while the latter is a “multidict” which allows multiple
values to be associated with a key. The same applies to the \texttt{orddict} and \texttt{ordmdict} types.

In addition, there are various supertypes which correspond to different unions of the hashed and ordered dictionary types. These are:

\begin{verbatim}
type hashxdict
type ordxdict
  Denotes any kind of hashed or ordered dictionary, respectively.
type stldict
type stlmdict
  Denotes any kind of singled-valued or multi-valued dictionary, respectively.
type stlxdict
  Denotes any kind of dictionary.
\end{verbatim}

For instance, you can use \texttt{hashxdict} to match both \texttt{hashdict} and \texttt{hashmdict} values. Likewise, \texttt{stlmdict} matches both \texttt{hashdict} and \texttt{orddict} values. To match any kind of dictionary, use the \texttt{stlxdict} type.

These data structures are very thin wrappers around the C++ container types; in fact, they are just pointers to the C++ containers. Memory management of these objects is automatic, and customizable \texttt{pretty-printing} is provided as well.

All data structures offer most of the usual Pure container interface (as well as some extensions). In contrast to the standard library dictionaries, they can be used both as dictionaries (holding key => value pairs) and sets (holding only keys, without associated values), even at the same time.

The other important difference to the standard library containers is that the stldict containers are \texttt{mutable} data structures; inserting and deleting members really modifies the underlying C++ containers. (However, it is possible to take copies of the containers in situations where it’s necessary to preserve value semantics.)

\section*{10.5 Operations}

All types of dictionaries are simply pointers to the corresponding C++ containers which hold key-value associations where both keys and values may be arbitrary Pure expressions. The basic operations described below can be used to create, query and modify these objects. Comparisons of dictionaries are implemented as well, and the set-like operations let you combine dictionaries in different ways. These operations provide an interface similar to the usual Pure container API.

In addition, the \texttt{stldict} module provides some list-like operations on dictionaries, so that the member data can be processed and aggregated in a convenient fashion (including the ability to use dictionaries as generators in list and matrix comprehensions), and there’s also an interface to C++ iterators which enables you to traverse, inspect and modify the containers in a more C++-like way. Some low-level operations are available to access information about the underlying hash table of a hashed dictionary. Last but not least, the module also offers some operations to customize the \texttt{pretty-printing} of dictionary values.
When working with these data structures, please note the following special properties of this implementation:

- All dictionary types are *mutable*. Inserting and deleting members really modifies the underlying C++ data structure as a side effect of the operation. If you need value semantics, you should probably use one of the dictionary or set data structures from the standard Pure library instead. Another possibility is to take a copy of a hashdict using the `copy` function if you need to preserve the original value.

- Keys in a hashed dictionary may be stored in an apparently random order (not necessarily in the order in which they were inserted), while they are guaranteed to be in ascending order (by key) for ordered dictionaries. However, note that even in the latter case, the order of different members for the same key in a multi-valued dictionary is not specified. This must be taken into account when comparing dictionaries, see below. The order of members in a dictionary also matters when listing data from a container using, e.g., the `members`, `keys` and `vals` operations.

- Two dictionaries are considered syntactically equal iff they contain the same elements in exactly the same order, using syntactic equality on both the keys and the associated values. This test can always be done in linear time, but is of limited usefulness for most kinds of dictionaries, since the exact order of members in the dictionary may vary depending on how the dictionary was constructed. Semantic equality operations are provided which check (albeit at the cost of increased running time) whether two containers contain the same members irrespective of element order, using semantic equality on the members. Various subset comparisons are provided as well, please check the *Comparisons* section for details.

- Values in a dictionary can be omitted, so that a dictionary can also be used as a set data structure. This obviates the need for a separate set data structure at the cost of some (small) increase in memory usage. Also note that you can’t really have a hash pair `x=>y` as a member of a set, since it always denotes a key-value association. As a remedy, you may use ordinary pairs `(x,y)` instead.

### 10.5.1 Basic Operations

```
hashdict xs
hashmdict xs
orddict xs
ordmdict xs
```

Create a dictionary of the corresponding type from a list, tuple or vector of its members. Members can be specified as hash pairs `x=>y` to denote a key-value association. Any other kind of value denotes a singleton key without associated value. Note that the ordered dictionaries require that the keys be ordered, i.e., the `<` predicate must be defined on them.

The same operations can also be used to construct a dictionary from another dictionary of any type. If the given dictionary is already of the corresponding type, this is a no-op (if you want to copy the dictionary instead, use the `copy` function below). Otherwise the given dictionary is converted to a new dictionary of the desired target type.
mkhashdict y xs
mkhashmdict y xs
mkorddict y xs
mkordmdict y xs

Create a dictionary from a list of keys and a constant value. The resulting dictionary has the given keys and y as the value for each key.

copy m

Create a new dictionary with the same type and content as m. This is useful if you want to preserve value semantics when using destructive update operations such as insert and delete. In such a case, copy can be used to take a copy of the dictionary beforehand, so that the original dictionary remains unmodified.

Note: This operation needs linear time with respect to the size of the dictionary (i.e., its number of members). If logarithmic update times are needed while still preserving value semantics, you should use the dictionary and set data structures from the standard library instead.

hashdictp m
hashmdictp m
orddictp m
ormddictp m

Check whether the argument is a dictionary of the corresponding type.

hashxdictp m
ordxdictp m
stldictp m
stlmdictp m
stlxdictp m

Check whether the argument is a dictionary of the corresponding supertype.

# m

The size of a dictionary (the number of members it contains).

m ! x

Get the value stored under key x in the dictionary m. This may be x itself if x is a member of m but has no associated value. In the case of a multidict this actually returns a list of values (which may be empty if m doesn’t contain x). Otherwise an out_of_bounds exception is thrown if m doesn’t contain x.

null m

Test whether m is empty, i.e., has zero members.

member m x

Test whether m contains a member with key x.

members m
list m

Return the list of members of m. The member list will be in an apparently random
order in the hashed dictionary case, while it is guaranteed to be in ascending order (by key) for ordered dictionaries. The same order is also used for the other inspection operations below.

**stream** m
Like **list**, but the member list is returned as a lazy list (cf. *Lazy Evaluation and Streams*) whose members will be computed on the fly as the list is being traversed; cf. **Iterators**.

**tuple** m
**vector** m
Return the member list as a tuple or vector.

**keys** m
Return the list of keys in the dictionary.

**vals** m
Return the list of corresponding values. In the case of a singleton key x without associated value, x itself is returned instead.

As already mentioned, the following modification operations are destructive, i.e., they actually modify the underlying dictionary data structure. If this is not desired, you’ll first have to take a copy of the target dictionary, see **copy**.

**insert** m x
**insert** m (x=>y)
**update** m x y
Insert a singleton key x or a key-value pair x=>y into m and return the modified dictionary. This always adds a new member in a multidict, otherwise it replaces an existing value if there is one. **update** is provided as a fully curried version of **insert**, so update m x y behaves exactly like insert m (x=>y).

**delete** m x
**delete** m (x=>y)
Remove the key x or the specific key-value pair x=>y from m (if present) and return the modified dictionary. In the multidict case, only the first member with the given key x or key-value pair x=>y is removed.

**clear** m
Remove all members from m, making m an empty dictionary. Returns ()

### 10.5.2 Comparisons

The usual comparison predicates (==, -=, <=, < etc.) are defined on all dictionary types, where two dictionaries are considered “equal” (m1==m2) if they both contain the same key=>value pairs, and m1<=m2 means that m1 is a sub-dictionary of m2, i.e., all key=>value pairs of m1 are also contained in m2 (taking into account multiplicities in the multidict case). Ordered dictionaries compare keys using equality (assuming two keys a and b to be equal if neither a<b nor b<a holds), while hashed dictionaries check for syntactical equality (using ===). The associated values are compared using the == predicate if it is defined, falling back to syntactic equality otherwise.
The module also defines syntactic equality on all dictionary types, so that two dictionaries of the same type are considered syntactically equal iff they contain the same (syntactically equal) members in the same order. This is always guaranteed if two dictionaries are “identical” (the same C++ pointer), but generally the member order will depend on how the dictionary was constructed. Thus if you need to check that two dictionaries contain the same members irrespective of the order in which the members are listed, the semantic equality operation \(==\) should be used instead; this will also handle the case of mixed operand types.

Note that if you really need to check whether two dictionaries are the same object rather than just syntactically equal, you’ll have to cast them to generic C pointers before comparing them with \(===\). This can be done with the following little helper function:

\[
\text{same_dict } x \text{ y } = \text{pointer_cast } "\text{void*}" \text{ x } === \text{pointer_cast } "\text{void*}" \text{ y};
\]

### 10.5.3 Set-Like Operations

These operations work with mixed operand types, promoting less general types to more general ones (i.e., ordered to hashed, and single-valued to multi-valued dictionaries). The result is always a new dictionary, leaving the operands unmodified.

\[m1 + m2\]

Sum: \(m1+m2\) adds the members of \(m2\) to \(m1\).

\[m1 - m2\]

Difference: \(m1-m2\) removes the members of \(m2\) from \(m1\).

\[m1 * m2\]

Intersection: \(m1*m2\) removes the members not in \(m2\) from \(m1\).

### 10.5.4 List-Like Operations

The following operations are all overloaded so that they work like their list counterparts, treating their dictionary argument as if it was the member list of the dictionary:

- do, map, catmap, listmap, rowmap, rowcatmap, colmap, colcatmap
- all, any, filter, foldl, foldll, foldr, foldrl, scanl, scanll, scanr, scanrl, sort

Note that this includes the generic comprehension helpers listmap, catmap et al, so that dictionaries can be used as generators in list and matrix comprehensions as usual (see below for some examples).

### 10.5.5 Iterators

These operations give direct access to C++ iterators on dictionaries which let you query the elements and do basic manipulations of the container. The operations are available in the stddict namespace.

The iterator concept is somewhat alien to Pure and there are some pitfalls (most notably, destructive updates may render iterators invalid), but the operations described here are still
useful in some situations, especially if you need to speed up sequential accesses to large containers or modify values stored in a container in a direct way. They are also used internally to compute lazy member lists of containers (stream function).

You should only use these directly if you know what you are doing. In particular, make sure to consult the C++ standard library documentation for further details on C++ iterator usage.

The following operations are provided to create an iterator for a given dictionary:

- `stldict::begin m`
- `stldict::end m`

  Return iterators pointing to the beginning and the end of the container. (Note that `stldict::end` must always be specified in qualified form since `end` is a keyword in the Pure language.)

- `stldict::find m x`

  Locates a key or specific key=>value pair x in the container and returns an iterator pointing to the corresponding member (or `stldict::end m` if m doesn’t contain x).

Note that these operations return a new iterator object for each invocation. Also, the created iterator object keeps track of the container it belongs to, so that the container isn’t garbage-collected while the iterator is still being used. However, removing a member from the container (using either `delete` or `stldict::erase`) invalidates all iterators pointing to that member; the result of trying to access such an invalidated iterator is undefined (most likely your program will crash).

Similar caveats also apply to the stream function which, as already mentioned, uses iterators internally to implement lazy list traversal of the members of a dictionary. Thus, if you delete a member of a dictionary while traversing it using stream, you better make sure that this member is not the next stream element remaining to be visited; otherwise bad things will happen.

The following operations on iterators let you query and modify the contents of the underlying container:

- `stldict::dict i`

  Return the dictionary to which i belongs.

- `stldict::endp i`

  Check whether the iterator i points to the end of the container (i.e., past the last element).

- `stldict::next i`

  Advance the iterator to the next element. Note that for convenience, in contrast to the corresponding C++ operation this operation is non-destructive. Thus it actually creates a new iterator object, leaving the original iterator i unmodified. The operation fails if i is already at the end of the container.

- `stldict::get i`

  Retrieve the key=>val pair stored in the member pointed to by i (or just the key if there is no associated value). The operation fails if i is at the end of the container.
stldict::put i y

Change the value associated with the member pointed to by i to y, and return the new value y. The operation fails if i is at the end of the container. Note that stldict::put only allows you to set the associated value, not the key of the member.

stldict::erase i

Remove the member pointed to by i (this invalidates i and all other iterators pointing to this member). The operation fails if i is at the end of the container.

i == j
i != j

Semantic equality of iterators. Two iterators are considered equal (i == j) if i and j point to the same element in the same container, and unequal (i != j) if they don’t. (In contrast, note that iterators are in fact just pointers to a corresponding C++ data structure, and thus syntactical equality (i == j) holds only if two iterators are the same object.)

10.5.6 Low-Level Operations

The hashdict module also provides a few specialized low-level operations dealing with the layouts of buckets and the hash policy of the hashdict and hashmdict containers, such as bucket_count, load_factor, rehash etc. These operations, which are all kept in their own separate hashdict namespace, are useful to obtain performance-related information and modify the setup of the underlying hash table. Please check the hashdict.pure module and the C++ standard library documentation for further details.

10.5.7 Pretty-Printing

By default, dictionaries are pretty-printed in the format some dict xs, where some dict is the actual construction function such as hashdict, orddict, etc., and xs is the member list of the dictionary. This is usually convenient, as the printed expression will evaluate to an equal container when reentered as Pure code. However, it is also possible to define your own custom pretty-printing with the following function.

hashdict_symbol f
hashmdict_symbol f
orddict_symbol f
ordmdict_symbol f

Makes the pretty-printer use the format f xs (where xs is the member list) for printing the corresponding type of dictionary.

Note that f may also be an operator symbol (nonfix and unary symbols work best). In the case of an outfix symbol the list brackets around the members are removed; this makes it possible to render the container in a format similar to Pure’s list syntax. For instance:

> using stldict;
> outfix ($ $);
> orddict_symbol ({$ $});
()
> orddict (1..5);
{1,2,3,4,5}$}

See orddict_examp.pure included in the distribution for a complete example which also discusses how to make such a custom print representation reparsable.

## 10.6 Examples

Some basic examples showing `hashdict` in action:

```pure
> using stldict;
> let m = hashdict [foo=>99, bar=>bar 4711L, baz=>1..5]; m;
hashdict [foo=>99, bar=>bar 4711L, baz=>[1,2,3,4,5]]
> m!bar;
bar 4711L
> keys m;
[foo, bar, baz]
> vals m;
[99, bar 4711L, [1,2,3,4,5]]
> list m;
[foo=>99, bar=>bar 4711L, baz=>[1,2,3,4,5]]
> member m foo, member m bar;
1,1
```

Hashed multidicts (`hashmdict`):

```pure
> let m = hashmdict [foo=>99, baz=>1..5, baz=>bar 4711L]; m;
hashmdict [foo=>99, baz=>[1,2,3,4,5], baz=>bar 4711L]
> m!baz;
[[1,2,3,4,5], bar 4711L]
> m!foo;
[99]
```

The following example illustrates how to employ ordered dictionaries (`orddict`) as a set data structure:

```pure
> let m1 = orddict [5,1,3,11,3];
> let m2 = orddict (3..6);
> m1+m2;
orddict [1,3,5,11]
orddict [3,4,5,6]
> m1+m2;
orddict [1,3,4,5,6,11]
> m1-m2;
orddict [1,11]
> m1*m2;
orddict [3,5]
> m1*m2 <= m1, m1*m2 <= m2;
1,1
> m1 < m1+m2, m2 < m1+m2;
1,1
```
Of course, the same works with ordered multidicts (`ordmdict`):

```plaintext
> let m1 = ordmdict [5,1,3,11,3];
> let m2 = ordmdict (3..6);
> m1+m2;
| ordmdict [1,3,3,5,11]  
| ordmdict [3,4,5,6]  
| m1+m2;  
| ordmdict [1,3,3,4,5,5,6,11]  
| m1-m2;  
| ordmdict [1,3,11]  
| m1+m2;  
| ordmdict [3,5]  
| m1*m2 <= m1, m1*m2 <= m2;  
| 1,1  
| m1 < m1+m2, m2 < m1+m2;  
| 1,1
```

In fact, the binary operations (comparisons as well as the set operations `+`, `-` and `*`) work with any combination of dictionary operands:

```plaintext
> let m1 = hashdict (1..5);
> let m2 = ordmdict (3..7);
> m1+m2;
| hashmdict [1,2,3,3,4,4,5,5,6,7] 
```

Note that the operands are always promoted to the more general operand type, where hashed beats ordered and multi-valued beats single-valued dictionaries. If this is not what you want, you can also specify the desired conversions explicitly:

```plaintext
> m1+orddict m2;
| hashdict [1,2,3,4,4,5,5,6,7] 
> orddict m1+m2;
| ordmdict [1,2,3,4,4,5,5,6,7] 
```

Also note that the “set” operations not only work with proper sets, but also with general dictionaries:

```plaintext
> hashdict [i=>i+1|i=1..4]+hashdict [i=>i-1|i=3..5];
| hashdict [1=>2,2=>3,3=>2,4=>3,5=>4] 
```

All dictionary containers can be used as generators in list and matrix comprehensions:

```plaintext
> let m = hashmdict [foo=>99,baz=>1..5,baz=>bar 4711L];
> [x y | x=>y = m];
| [foo 99,baz [1,2,3,4,5],baz (bar 4711L)]  
> {{x;y} | x=>y = m};
| {foo,baz,baz;99,[1,2,3,4,5],bar 4711L} 
```

Note that in the current implementation this always computes the full member list of the dictionary as an intermediate value, which will need considerable extra memory in the case of large dictionaries. As a remedy, you can also use the `stream` function to convert the dictionary to a lazy list instead. This will often be slower, but in the case of big dictionaries...
the tradeoff between memory usage and execution speed might be worth considering. For instance:

```plaintext
> let m = hashdict [foo i => i | i = 1..10000];
> stream m;
(foo 1512=>1512):#<thunk 0x7fa1718350a8>
> stats -m
> #list m;
10000
0.01s, 40001 cells
> #stream m;
10000
0.1s, 16 cells
> #[y | x=>y = m; gcd y 767~=1];
925
0.05s, 61853 cells
> #[y | x=>y = stream m; gcd y 767~=1];
925
0.15s, 10979 cells
```
pure-stllib

Version 0.6, April 11, 2018

Peter Summerland <p.summerland@gmail.com>

pure-stllib is an “umbrella” package that contains a pair of Pure addons, pure-stlvec and pure-stlmap. These addons provide Pure interfaces to a selection of containers provided by the C++ Standard Library, specialized to hold pointers to arbitrary Pure expressions. pure-stlvec is a Pure interface to C++’s vector and the STL algorithms that act on them. pure-stlmap is an interface to six (of the eight) of C++’s associative containers: map, set, multimap, multiset, unordered_map and unordered_set.

11.1 Copying

Copyright (c) 2011-2012 by Peter Summerland <p.summerland@gmail.com>.

All rights reserved.

pure-stllib is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

pure-stllib is distributed under a BSD-style license, see the COPYING file for details.

11.2 Installation

pure-stllib-0.6 requires at least Pure 0.50. The latest version of Pure is available at https://bitbucket.org/purelang/pure-lang/downloads.
The latest version of the source code for pure-stlib can be downloaded from https://bitbucket.org/purelang/pure-lang/downloads/pure-stlib-0.6.tar.gz.

To install pure-stlib-0.6 (on Linux), extract the source code (e.g., tar -xzf pure-stlib-0.6.tar.gz), cd to the pure-stlib-0.6 directory, and run make. After this you can (and should) also run make check to run a few unit tests to make sure that pure-stlvec and pure-stlmap work properly on your system. If make check works, run sudo make install to install pure-stlvec and pure-stlmap. Run sudo make uninstall to remove them.

make tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, make install prefix=/usr sets the installation prefix. Please see the Makefile for details.

11.3 Usage

pure-stlvec provides functions that act on a single mutable container, stlvec, which is a wrapper around C++’s vector, specialized to hold Pure expressions. It also provides functions that correspond to C++’s STL algorithms specialized to act on stlvecs.

pure-stlmap provides functions that act on six mutable containers, “stlmap”, “stlset”, “stlmmap”, “stlmset”, “stlhmap” and “stlhset”, that are thin wrappers around the corresponding associative containers provided by C++, map, set, multimap, multiset, unordered_map and unordered_set, specialized to hold Pure expressions.

The functions provided by pure-stlvec and pure-stlmap are made available by importing one or more of the following modules.

- stlvec - support for stlvecs
- stlvec::algorithms - STL algorithms specialized to act on stlvecs
- stlmap - support for stlmap and stlset
- stlmmap - support for stlmmap and stlmset
- stlhmap - support for stlhmap and stlhset

11.4 Documentation

Please see the documentation for pure-stlvec and pure-stlmap.

For the impatient, the functions that act on containers provided by the stlmap, stlmmap, stlhmap and stlvec modules are summarized in a rudimentary cheatsheet, pure-stllib-cheatsheet.pdf, which can be found in the pure-stllib/doc directory.

11.5 Changes

Version 0.1 - Bundle pure-stlvec-0.3 and pure-stlmap-0.1.

Version 0.2 - Bundle pure-stlvec-0.3 and pure-stlmap-0.2.
Version 0.3 - Bundle pure-stlvec-0.4 and pure-stlmap-0.3.
pure-stlmap

Version 0.4, April 11, 2018

Peter Summerland <p.summerland@gmail.com>

pure-stlmap is a Pure interface to six associative containers provided by the C++ Standard Library: map, set, multimap, multiset, unordered_map and unordered_set.

12.1 Copying

Copyright (c) 2012 by Peter Summerland <p.summerland@gmail.com>

All rights reserved.

pure-stlmap is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

pure-stlmap is distributed under a BSD-style license, see the COPYING file for details.

12.2 Introduction

This is pure-stlmap-0.1, the first release of pure-stlmap. It is possible that some of the functions might be changed slightly or even removed. Comments and questions would be especially appreciated at this early stage.
12.2.1 Supported Containers

The Standard C++ Containers Library, often referred to as the standard template library ("STL"), provides templates for generic containers and generic algorithms. pure-stlmap provides six mutable containers, "stlmap", "stlset", "stlmmap", "stlmsset", "stlhmap" and "stlhset", that are thin wrappers around the corresponding associative containers provided by the STL, map, set, multimap, multiset, unordered_map and unordered_set, specialized to hold pure-expressions. pure-stlmap does not provide wrappers for unordered_multimap and unordered_multiset.

12.2.2 Interface

pure-stlmap provides a "key-based" interface that can be used to work with the supported STL containers in a way that should feel natural to Pure programmers. For example, the (!) function can be used to access values associated with keys and functions like map, foldl, filter and do can be used to operate on all or part of a container’s elements without using an explicit tail recursive loop. In addition, for the ordered containers, stlmap, stlmmap, stlset and stlmsset, pure-stlmap provides an "iterator-based" interface that corresponds to the C++ interface, mostly on a one-to-one basis.

The interface for the unordered or "hash table" containers, stlhmap and stlhset, is limited compared to that provided for the ordered containers. In particular iterators, operations on subsequences (ranges) and set operations are not supported.

In some cases, the STL’s associative containers have different semantics than the the associative containers provided by the Pure standard library. Where there is a conflict, pure-stlmap follows the STL.

Many of the functions provided by pure-stlmap, such as the constructors, equivalence and lexicographical comparison operations, insert and erase operations, and the set operations are just thin wrappers around the the corresponding C++ functions. Users can consult the C++ Library documentation to understand the performance characteristics and corner case behavior of any pure-stlmap function that has a corresponding function in the STL.

The C++ library is sometimes more complicated than the Pure Standard Library. For example many of the applicable C++ functions, including set operations and tests for equality, assume that the containers are lexicographically ordered. The reward for playing by the rules (which occurs automatically for stlmap and stlset) is $O(n)$ time complexity for comparison and set operations.

12.3 Installation

pure-stlmap-0.4 is included in the “umbrella” addon, pure-stllib which is available at https://bitbucket.org/purelang/pure-lang/downloads. After you have downloaded and installed pure-stllib, you will be able to use pure-stlmap (and pure-stlvec, as well).
12.4 Examples

The pure-stlmap/uts subdirectory contains Pure scripts that are used to test pure-stlmap. These scripts contain simple tests, each of which consists of a single line of code followed by a comment that contains the expected output. E.g.,

```pure
let sm1 = stlmap ["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5];
// - ()
sm1!stl::smbeg, sm1!"a", sm1!"d", sm1!"e"
// - 1,1,4,5
```

You might consider pasting parts of these scripts into a temporary file that you can play with if you are curious about how something works.

Two short example programs, anagrams.pure and poly.pure, can be found in the pure-stlmap/examples subdirectory.

12.5 Quick Start

This section introduces the basic functions you need to get up and running with pure-stlmap. For a quick look at the other functions provided by pure-stlmap, you can refer to pure-stllib-cheatsheet.pdf, which can be found in the pure-stllib/doc directory.

12.5.1 Example Containers

The code snippets that appear in the examples that follow assume that six containers have been created by entering the following at the prompt.

```
$> pure -q
> using stlmap, stlhmap, stlmmap;
> using namespace stl;

> // Make some maps and sets with default characteristics
> let sm = stlmap ["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5];
> let shm = stlhmap ["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5];
> let smm = stlmmap ["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4,"e"=>5];
> let ss = stlset ["a","b","c","d","e"];
> let shs = stlhset ["a","b","c","d","e"];
> let sms = stlmset ["a","b","c","d"];
```

The using statement imports the three modules provided by pure-stlmap: stlmap provides the interface for the stlmap and stlset containers, stlmmap provides the interface the stlmmap and stlmset containers, and stlhmap provides the interface to the stlhmap and stlhset containers. The let statements set up an instance of each of the containers provided by pure-stlmap, loaded with some sample elements.
To save typing you can run readme-data.pure, a file that contains the corresponding source code. It can be found in in the pure-stlmap/examples directory.

### 12.5.2 Constructors

You can construct empty pure-stlmap containers using the `emptystlmap`, `emptystlset`, `emptystlmmap`, `emptystlmset`, `emptystlhmap` and `emptystlhset` functions.

```pure
> let sm1 = emptystlmap;  // uses (<) to order keys
```

You can construct a pure-stlmap container and fill it with elements all in one go using the `stlmap`, `stlset`, `stlmmap`, `stlmset`, `stlhmap` and `stlhset` functions.

```pure
> let shm1 = stlhmap ["a"=>1,"b"=>2,"c"=>3];

> members shm1;
["c"=>3,"a"=>1,"b"=>2]

> shm1!"b";
2
```

As opposed to the hashed containers (`stlhmap` and `stlhset`), the ordered containers (`stlmap`, `stlset`, `stlmmap` and `stlmset`) keep their elements ordered by key.

```pure
> let sm1 = stlmap ["a"=>1,"b"=>2,"c"=>3]; members sm1;
["a"=>1,"b"=>2,"c"=>3]
```

### 12.5.3 Ranges

For the ordered containers (`stlmap`, `stlset`, `stlmmap` and `stlmset`) you can work with subsequences, called “ranges”, of the containers’ elements. A range is specified by a tuple that consists of a container and two keys. If `(sm, first_key, last_key)` designates a range, the elements of the range are all of elements of the container `sm` whose keys are equivalent to or greater than `first_key` and less than `last_key`. If `first_key` and `last_key` are left out of the tuple, the range consists of all of `sm`’s elements.

```pure
> members sm;  // no range keys - the whole container
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]

> members (sm,"b","e");  // a range from "b" up but not including "e"
["b"=>2,"c"=>3,"d"=>4]

> members (sm,"c1","z");  // keys do not have to be stored
["d"=>4,"e"=>5]

> members shm;  // works on a unordered set (with no range keys)
["c"=>3,"d"=>4,"e"=>5,"a"=>1,"b"=>2]
```

Two special keys, `stl::smbeg` and `stl::smend` are reserved for use in ranges to designate the first element in a container and the imaginary “past-end” element.
Perhaps it should go without saying, but you cannot use either of these symbols as the keys of elements stored in a pure-stlmap container.

### 12.5.4 Inserting and Replacing Elements

You can insert elements and, for the maps (stlmap, stlmmmap and stlhmmap), replace the values associated with keys that are already stored in the map, using the `insert`, `replace` and `insert_or_replace` functions. For the maps, the elements to inserted are specified as (key=>value) hash-pairs.

```plaintext
> let sm1 = emptystlmap;
> members (sm, smbeg, "d");
["a"=>1, "b"=>2, "c"=>3]

> members (sm, "b", smend);
["b"=>2, "c"=>3, "d"=>4, "e"=>5]
```

The `insert` and `insert_or_replace` functions are overloaded to insert or replace elements specified in a list, vector, stlvec or another pure-stlmap container (of the same type). E.g.,

```plaintext
> let sm2 = emptystlmap;

> insert sm2 ["b"=>2, "a"=>1]; // insert from a list
2

> insert sm2 (sm, "c", "e"); // insert from a range
2
```
12.5.5 Access

If you want to see if a key is stored in a container use the member function. (A key, k, is considered to be “stored” in a container if there is an element in the container that is equivalent to k.)

> member sm "x"; // ("x"=>val) is not an element of sm for any val
>
> member sm "a"; // ("a"=>1) is an element with key equivalent to "a"

The value (or values for a multi-key container) associated with a key can be accessed using the (!) function.

> sm!"a"; // return the value associated with "a"
>
> shm!"b"; // try it with a hashed map

> smm!"c"; // multimap returns a the list of values associated with "c"
> [31,32]

> ss!"a"; // with sets, return the key "a"

> sms!"c"; // with multisets, return a list of keys
> ["c","c"]

If the key is not stored in the container, (!) throws an out_of_bounds exception.

> catch id $ sm!"x"; // "x" is not stored as a key in sm
> out_of_bounds

Please note that all access is strictly by keys. For example you cannot use the member function to determine if ("a"=>1) is an element stored in sm; you can only ask if the key “a” is stored in sm.
12.5.6 Erasing Elements

For any pure-stlmap container, you can use the `erase` function to remove all the elements associated with a given key in the container, all of the elements in the container or, unless the container is a stlhmap or stlhset, all of the elements in a range defined on the container.

```cpp
> let shm1 = stlhmap shm;  // make some copies of maps
> let smm1 = stlmmap smm;
> let sm1 = stlmap sm;

> members smm1;  // smm1 has multiple values for "c"
["a"=>1, "b"=>2, "c"=>31, "c"=>32, "d"=>4, "e"=>5]

> erase (shm1,"c");  // erase "c" keyed elements from a stlmmap
1
> members shm1;  // all the "c" keyed elements are gone
["d"=>4, "e"=>5, "a"=>1, "b"=>2]

> erase shm1;  // erase all elements
4
> empty shm1;
1

> erase (sm1,"b","d");  // erase a subsequence
2
> members sm1;
["a"=>1, "d"=>4, "e"=>5]

> erase (sm1,"x");  // attempt to erase something not there
0

> erase (smm1,"c");  // erase all elements with key "c"
2
> members smm1;
["a"=>1, "b"=>2, "d"=>4, "e"=>5]
```

12.5.7 Conversions

The elements of an associated container be copied into a list, vector or stlvec using the `members`, `stl::vector` and `stlvec` functions. For ordered containers (stlmap, stlset, stlmmap and stlmset) the list, vector or stlvec can be built from a range.

```cpp
> members ss;
["a","b","c","d","e"]

> members (ss,"b","d"); // list subsequence from "b" up to but not "d"
["b","c"]

> members (smm,"c","e");
["c"=>31,"c"=>32,"d"=>4]

> members (shm,"b","d"); // fails - ranges not supported for stlhmaps
```
You can convert the contents of an ordered container (stlmap, stlset, stlmmap or stlmset) or a range defined on one to a stream using the `stream` function.

```pure
> let ss1 = stlhset (0..100000);
> stats -m
> let xx = drop 99998 $ scanl (+) 0 (stream ss);
0.3s, 18 cells
> list xx;
[704782707, 704882705, 704982704, 705082704]
0s, 17 cells
```

### 12.5.8 Functional Programming

Most of the Pure list operations, including `map`, `do`, `filter`, `catmap`, `foldl` and `foldl1` can be applied to any of pure-stlmap’s associative containers. E.g.,

```pure
> map (\x->x-32) shs;
["D","E","A","B","C"]
```

```pure
> using system;
> do (puts . str) (sm,smbeg,"c");
"a"=>1
"b"=>2
()
```

List comprehensions also work.

```pure
> [k-32=>v+100 | (k=>v) = smm; k>"a" & k<"e"];
["B"=>102, "C"=>131, "D"=>104]
```

```pure
> {k-32=>v+100 | (k=>v) = (smm,"b","e")};
{"B"=>102, "C"=>131, "D"=>104}
```

It is highly recommended that you use the functional programming operations, as opposed to recursive loops, whenever possible.
12.6 Concepts

This section describes pure-stlmap’s containers, iterators, ranges, elements, keys, values and how these objects are related to each other. It also describes a group of functions associated with containers that help define the container’s behavior. E.g., each ordered container (stlmap, stlset, stlmmmap or stlmmset) stores a function that it used to order its keys and to determine if two keys are equivalent.

12.6.1 Containers and Elements

The six associative containers supported by pure-stlmap can be grouped together in terms of certain defining attributes.

The three “maps” provided by pure-stlmap, stlmap, stlmmmap and stlhmap, associate values with keys. If a value v is associated with a key, k, in an map, m, then we say that (k=>v) is an element of m, k is a key stored in m and v is a value stored in m.

The three “sets” provided by pure-stlmap, stlset, stlmset and stlhset, hold single elements, as opposed to key value pairs. If an element e is contained a set, s, we say that e is simultaneously an element, key and value stored s. In other words, we sometimes speak of a set as if it were a map where each element, key and value are the same object.

The “ordered” containers, stlmap, stlset, stlmmmap and stlmset, each have a “key-less-than” function that they use keep their elements in a sequence that is ordered by keys. The default key-less-than function is (<), but this can be changed when the container is created. The elements stored in a stlmap or stlset have unique keys, i.e., two elements stored in the container will never have equivalent keys. For these purposes, two keys are “equivalent” if neither key is key-less-than the other. In contrast, stlmmmap and stlmset do not have unique keys. I.e., it is possible for different elements stored in a stlmmmap or stlmset can have equivalent keys.

The “hashed” containers, sthmap and stlhset do not keep their elements in a sequence. Instead they store their elements in a hash table using a “key-hash” function and a “key-equal” function. Currently the key-hash function is always hash and the key-equal function is always (===), both of which are defined in the Prelude. The elements stored in a hashed container have unique keys. I.e., two elements stored in the container will never by “key-equal”. At times we say that two keys stored in a hashed container are “equivalent” if they are key-equal.

The “ordered maps”, stlmap and stlmmmap, each have a “value-less-than” function and a “value-equal” function that is used for lexicographical comparisons. The default functions are (<) and (==) respectively, but these can customized when the container is created.

As is the case for the underlying C++ functions, set operations (i.e., union, intersection, etc.) and container equivalence for the ordered containers are based on lexicographical comparisons. For these purposes one element, e1, is less than another, e2, if (a) e1’s key is less-than e2’s key and, (b) if the ordered container is a stlmap or stlmmap, e1’s value is value-less-than e2’s value. Finally, for purposes of determining if two ordered containers are equal, e1 and e2 are considered to be equal if (a) their keys are equivalent and (b), in the case of stlmap or stlmmmap, their values are value-equal.
Set operations are not provided for the hashed containers, stlhashmap and stlhashset.

### 12.6.2 Ranges

For the ordered containers (stlmap, stlset, stlmmmap and stlmmset), you can work with a sub-sequence or “range” of a container’s elements. Given an ordered container, oc, and keys f and l, the range (oc,f,l) consists of all of the elements in oc starting with the first element that is not less than f up to but not including the first element that is greater or equal to l. Note that f and l do not have to be stored in oc.

```cpp
> members (sm,"b", "e");
["b"=>2, "c"=>3, "d"=>4]
```

```cpp
> members (sm,"c1", smend);
["d"=>4, "e"=>5]
```

When a range is passed to a function provided by pure-stlmap, the keys can be dropped, in which case the range consists of all of the container’s elements.

```cpp
> members sm;
["a"=>1, "b"=>2, "c"=>3, "d"=>4, "e"=>5]
```

Please note that support for ranges is not provided for the unordered containers (stlhashmap and stlhashset). Most pure-stlmap functions that act on ranges can, however, operate on stlhashmaps or stlhashsets as well, except that, for stlhashmaps and stlhashsets, they always operate on all of the container’s elements. Accordingly, whenever the documentation of a function refers to a range, and the container in question is a a stlhashmap or stlhashset, the range simply refers to the container itself.

### 12.6.3 Iterators

The native STL interface is based on “iterators” that point to elements in containers. pure-stlmap provides support for iterators defined on its ordered containers (stlmap, stlmmmap, stlset and stlmmset) but not for its unordered containers (stlhashmap and stlhashset).

Iterators are most useful when dealing with stlmmmaps where elements with different values can have equivalent keys. In most cases, it is recommended that you avoid using iterators. The functions that operate on or return iterators are discussed separately at the end of this document.

### 12.6.4 Selecting Elements Using Keys

Throughout pure-stlmap, unless you resort to using iterators, you can only specify elements and ranges of elements using keys. For example you cannot use the `member` function to see if a specific key, value pair is an element of a stlmap.

```cpp
> members sm;
["a"=>1, "b"=>2, "c"=>3, "d"=>4, "e"=>5]
```

```cpp
> member sm "a";
```
In the last line of code, `member` treats `(a=>1)` as a key. Because `(a=>1)` cannot be compared to a string using `<`, the ersatz key is treated as a bad argument.

This “key access only” approach can be an issue for stlmmaps and because multiple elements can have equivalent keys. I.e., given a stlmmmap, smm, that contains multiple element with keys equivalent to, say, `k`, which element should (!) return? pure-stlmap dodges this issue by returning all on them. Thus, for stlmmmap and stlmset (!) and `replace` work with lists of elements associated with a given key rather than, say, the first elment with the given key.

```plaintext
> members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4];

> smm!"c";
"c"=>[31,32]

> replace smm "c" [31,32,33]; members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"c"=>33,"d"=>4]

> replace smm "c" []; members smm;
["a"=>1,"b"=>2,"d"=>4,"e"=>5]
```

If selecting and replacing lists of elements with the same key is not convenient, you can always use iterators to track down and modify any specific element.

### 12.6.5 C++ Implementation

For those that want to refer to the C++ standard library documentation, stlmap is (essentially) `map<px*,px*>`, stlmmmap is `multimap<px*,px*>` and stlhmmmap is `unordered_map<px*,px*>`, where `px` is defined by “typedef pure_expr px”. I.e., in C++ Containers library speak, `key_type` is `px*`, `mapped_type` is `px*` and `value_type` is `pair<px*,px*>`. This might be a bit confusing because pure-stlmap’s `(key=>value)` “elements” correspond to C++ `value_types`, a `pair<key_type,mapped_type>`, and pure-stlmmmap’s values correspond to `mapped_types`. The C++ objects for stlset, stlmmset and stlhmmset are the same as stlmap, stlmmmap and stlhmmmap except that pure-stlmmmap ensures that the second member of the C++ `value_type` pair is always NULL.

### 12.7 Modules

pure-stlmmmap provides three separate modules `stlmap`, `stlmmmap` and `stlhmmmap`.

Importing any one of these modules defines the stl namespace as well as two important symbols, `stl::smbeg` and `stl::smend`.

```plaintext
constructor stl::smbeg
```

---

**12.6.5 C++ Implementation** 405
**constructor** std::smend

These symbols are used to designate the key of the first element in an ordered container (std::map, std::set, std::multimap or std::multiset) and the key of an imaginary element that would come immediately after the last element of in the container. They are used to define ranges over the ordered containers.

E.g.,

```cpp
> members sm;
{"a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5}

> members (sm,"c",smend);
{"c"=>3,"d"=>4,"e"=>5}
```

### 12.7.1 The stlhmmap Module

If all you want is fast insertion and lookup, you don't care about the order of the elements stored in the container, and you do not want to use set operations like `std::map_intersection`, then `stlhmmap` is probably your best choice. The supported containers, `stlhmmap` and `stlhmset` are simpler to use and faster than the other containers provided by pure-stlhmmap.

The `stlhmmap` module defines `stlhmmap`s and `stlhmset`s and provides functions for dealing with them. You can import it by adding the following using statement to your code.

```cpp
> using stlhmmap;
```

The `stlhmmap` module defines types two types:

```cpp
type stlhmmap
type stlhmset
```

Please note that a `stlhmset` is just a `stlhmmap` where the values associated with keys cannot be accessed or modified. I.e., a `stlhmset` is a specialized kind of `stlhmmap`.

### 12.7.2 The stlhmmap Module

The `stlhmmap` module provides you with `stlhmmap`s and `stlhmset`s and the functions that operate on them. Consider using these containers if you want their elements to be ordered by key, want to use ranges or if you are using any set operations (`std::map_union`, `std::map_intersection`, etc).

You can import the `stlhmmap` module by adding the following using statement to your code.

```cpp
> using stlhmmap;
```

Importing the `stlhmmap` module introduces types to describe `stlhmmap` and `stlhmset`, their iterators and ranges defined on them.

```cpp
type stlhmmap
type stlhmset
```
type stlmap_iter

type stlmap_rng

Please note that a stlset is just a stlmap where the values associated with keys cannot be accessed or modified. I.e., a stlset is a specialized kind of stlmap. Accordingly, it is not necessary, for example, to define a separate type for iterators on stlsets as opposed to iterators on stlmaps.

### 12.7.3 The stlmmap Module

If you need a multi-keyed container, the stlmmap module, which provides support for stlmaps and stlmsets, is your only choice. Set operations and ranges are supported, but the semantics are more complicated than is the case for stlmap and stlset. Because the keys stored in multi-keyed containers are not unique you might have to resort to using iterators when working with them.

You can import the stlmmap module by adding the following using statement to your code.

```cpp
using stlmmap;
```

Importing the stlmmap module introduces types to describe stlmmmap and stlmset, along with their iterators and ranges defined on them.

```cpp
type stlmmmap

type stlmset

type stlmmmap_iter

type stlmmmap_rng
```

Please note that a stlmset is just a stlmmap where the values associated with keys cannot be accessed or modified. I.e., a stlmset is a specialized kind of stlmmap. Accordingly, it is not necessary, for example, to define a separate type for iterators on stlmsets as opposed to iterators on stlmmmaps.

### 12.8 Container Operations

Each of the six associative containers supported by pure-stlmap has its own set of unique characteristics. Because of this the description of functions that operate on more than one type of container can get a little complicated. When reading this section it might be helpful to consult pure-stllib-cheatsheet.pdf which can be found in the pure-stllib/doc directory.

#### 12.8.1 Container Construction

New empty ordered containers (stlmap, stlset, stlmmmap and stlmset) can be constructed using optional parameters that allow you to specify customized key-less-than functions, default values, value-less-than and value-equal functions.

```cpp
mkstlmap(klt,dflt,vlt,veq)
```
**mkstlmmap** *(klt,dflt,vlt,veq)*

Create a new stlmap or stlmmap where *klt* is the map’s key-less-than function. *dflt* is the map’s default value (used by replace_with and find_with_default). *vlt* is the map’s value-compare function and *veq* is its value-equal function. Only *klt* is required, and the default values for *dflt*, *vlt*, *veq* are [], (<) and (==) respectively.

**mkstlset** *klt*

**mkstlmsset** *klt*

Create a new stlset or stlmset where *klt* is the set’s key-less-than function.

The internal lookup functions for the ordered containers (stlmap, stlset, stlmmap and stlmset) are optimized to avoid callbacks if the container’s key-less-than function is is (>) or (<) and the keys being compared are a pair of strings, ints, bigints or doubles.

You can create an empty associative container using default values for using `emptystlmap` and friends.

**emptystlmap**

**emptystlmmap**

**emptystlset**

**emptystlmset**

Create a new ordered map or set using default values. I.e., emptystlmap is the same as mkstlmap (<), and so on.

**emptystlhmmap**

**emptystlhmset**

Create a new stlhmap or stlhset with default values. The hash-function is hash and the value-equal function is (===).

Convenience functions are also provided to construct an empty container and insert elements into it in one go. The source of the elements can be a list, vector, a stlvec, or a range defined on another container of the same type as the new container.

**stlmap** *src*

**stlmmmap** *src*

**stlset** *src*

**stlmset** *src*

**stlhmap** *src*

**stlhset** *src*

Create an associative constructor using default values and insert elements from copied from *src*. *src* can be a list, vector or stlvec of elements or a range defined over a container of the same type as the new container. If the new container is a stlmap, stlmmmap or stlhmap, the elements of *src* must be (key=>val) pairs. If the new container is a stlset, stlmset or stlhset they can be any pure expression that can be used as a key (i.e., anything except for stl::smbeg or stl::smend).

### 12.8.2 Information

This group of functions allows you to make inquiries regarding the number of elements in a container, the number of instances of a given key held by a container, the upper and lower
bounds of a range and other information. In addition this group includes a function that can be used to change the number of slots used by a stlhpmap or stlhsset.

#acon
Return the number of elements inacon.

stl::emptyacon
Return true ifacon is empty, else false.

stl::distancerng
Returns the number of elements contained inrng where rng is a range defined on an ordered container (stlmap, stlmmmap, stlset, stlmsset).

stl::countacon k
Returns the number of elements in an associative container,acon, that have a key that is equivalent to k.

stl::boundsrng
Return a pair of keys, first and last, such that first <= k < last for each k, where k is the key of an element in rng. If there is no such last, the second member of the returned pair will be stl::smend. If first is the key of the first element of rng’s container, the first member of the returned pair will stl::smbeg.

Here are two examples using the stl::bounds function. Notice that bounds returns stl::smbeg instead of “a” in the first example.

> members sm;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]

> bounds sm;
stl::smbeg, stl::smend

> bounds (sm,"a1","e");
"b","e"

stl::container_infoacon
Ifacon is a stlmap or stlmmmap, returns (0, klt, dflt, vlt, veq) where klt isacon’s key-less-than function, dflt is its default value, vlt is its value-less-than function and veq is its value_equal function. Ifacon is a stlset or stlmsset, returns (1, klt, ___, ___) where klt isacon’s key-less-than function. Ifacon is a stlhpmap or stlhsset, returns (is_set, bucket_count, load_factor, max_load_factor).

stl::bucket_sizenhacon n
Returns the number of elements in hacon’s nth (zero-based) bucket wherehacon is a stlhpmap or stlhsset.

stl::hmap_reservehacon mlf size
Sets hacon’s max_load_factor to mlf, sets the number of hacon’s buckets to ‘‘size/mlf’ and rehashes ‘‘hacon where hacon is a stlhpmap or stlhsset.
12.8.3 Modification

You can insert new items or, for the maps (stlmap, stllmap and stlhmap), replace values associated with keys using the `insert`, `replace` or `insert_or_replace` functions.

Please note that when working with the ordered containers (stlmap, stlset, stllmap and stlmset) the keys of elements passed to these functions must be compatible with the container’s key-less-than function and keys that are already inserted. E.g.,

```
> members ss;
["a","b","c","d","e"]

> catch id $ insert ss 1;  // e.g., 1<"a" is not defined
bad_argument
```

Currently there is no similar restriction for stlhmaps and stlhsets because (a) they do not have a key-less-than function and (b) the function they do use for testing equality, the key-equal function is always (===), a function that can compare any two objects.

```
> members shs;
["c","d","e","a","b"]

> insert shs 1;  1

> members shs;
["c",1,"d","e","a","b"]
```

Elements can be inserted into a pure-stlmap container individually or en masse from a list, vector, stlvec or another container of the same type. If there is a key in the container that is equivalent to the key of the element being inserted, the element will not be inserted (unless the container is a stllmap or stlmset, both of which can hold multiple elements with equivalent keys).

**insert** acon src

Attempts to copy elements from src a valid “insert source” into acon which can be any pure-stlmap container. A valid insert source is (a) a single element, (b) a list, vector, stlvec of elements or (c), a range over an associative container of the same type as acon. If acon is an associative map (stlmap, stllmap or stlhmap), the src itself, or all the elements of src, must be key value pairs of the form (k=>v). In contrast, if acon is a stlset, stlmset or stlhset, src or all of its elements can be any pure object (except `stl::smbeg` or `stl::smend`). If acon is a stlmap, stlset, stllmap or stlmset, the element will not be inserted if its key is already stored in the target container. Returns the number of elements inserted, if any.

If you are dealing with a stlmap or stlhmap and want to override the values of elements have keys that equivalent to the keys of the items you wan to insert you can use the `insert_or_replace` function.

**insert_or_replace** acon src

The same as `insert` except that (a) acon must be a stlmap or a stlhmap and (b) if an element (key=>newval) is about to be inserted and the container already contains an
element (key=>oldval) the element in the container will be changed to (key=>newval). Returns the number of elements inserted or updated.

**replace** map key x

map must be a stlmap, stlmmmap or stlhmap. If key is not stored in map this function throws out_of_bounds. If map is a stlmap or stlhmap and (oldkey=>oldval) is an element of map, where oldkey is equivalent to key, change the element to (oldkey=>'x'). If map is a stlmmmap and key is stored in map, change the values of elements with key equivalent to key, one by one, to the elements of x. Add or delete elements as necessary so that, when the smoke clears, the values of map!'key' are copies of the elements of x. In all cases, if key is stored in map returns x.

Here are some examples using replace.

```plaintext
> members sm1;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]

> replace sm1 "e" 50;
50

> members sm1;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>50]

> members smm1;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4,"e"=>5]

> replace smm1 "c" [31,33,35,36] $ smm1!"c";
[31,33,35,36]

> replace smm1 "c" [] $ smm1!"c";
[]

> members smm1;
["a"=>1,"b"=>2,"d"=>4,"e"=>5]
```

**replace_with** fun map (k=>v)

map must be a stlmap. The effect of this function is as follows: (a) if ~ member map k then insert map (k''=>dflt) else (), where dflt is 'map's dflt value, (b) replace map k nv when nv = fun v (map!'k') end. Returns map.

Here is an example using replace_with in which a stlmmmap is converted to a stlmap.

```plaintext
> let sm1 = emptystlmap;

> members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4,"e"=>5]

> do (replace_with (:) sm1) smm;
()

> members sm1;
["a"=>1,"b"=>2,"c"=>32,31,"d"=>4,"e"=>5]
```

12.8.3 Modification
Here is another example in which items are counted.

```haskell
> let sm1 = mkstlmmap ( (<), 0 );

> members sms;
["a","b","c","c","d"]

> do (\x->replace_with (+) sm1 (x=>1)) sms;
()

> members sm1;
["a"=>1,"b"=>1,"c"=>2,"d"=>1]
```

You can remove all the elements in a container, remove all the elements equivalent to a given key or a remove a range of elements using the `erase` function.

```haskell
erase acon
erase (acon,k)
erase (acon,k1,k2)
```

The first form erases all elements in `acon` which can be any container provided by pure-stlmmap. The second erases all elements in `acon` with key equivalent to `k`. The third erases the elements in the range (acon,"k1","k2"). The third form only applys to the ordered containers (stlmmap, stlmset, stlset and stlmset), not stlmmap or stlhset (because ranges are not defined for stlmaps or stlhsets). Returns the number of elements removed from the container.

Here are some examples using `erase`.

```haskell
> members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4,"e"=>5]

> erase (sm,"z");
0

> erase (smm,"c");
2

> members smm;
["a"=>1,"b"=>2,"d"=>4,"e"=>5]

> erase (smm,"b","e");
2

> members smm;;
["a"=>1,"e"=>5]
```

```haskell
stl::swap acon1 acon2
```

Swaps the elements of the two containers, `acon1` and `acon2` where `acon1` and `acon2` are the same type of container (E.g., both are stlmaps or both are stlmsets).
12.8.4 Accessing Elements

You can test if a key is stored in a container and access the value associated with a key using the familiar `member` and (!) functions.

**member** `acon k`

Returns true if `acon`, any container provided by pure-stlmap, contains an element that has a key that is equivalent to `k`.

**acon ! k**

If `acon` is not a stlmmmap then (a) if `acon` has an element with key equivalent to `k` return its value, otherwise (b) throw an `out_of_bounds` exception. If `acon` is a stlmmmap then (a) if `acon` has at least one element with key equivalent to `k` return a list of values of all the elements with key equivalent to `k`, otherwise (b) return an null list.

E.g.:

```
> sm!"c";
3

> catch id $ sm!"f"; // "f" is not stored in sm
out_of_bounds

> catch id $ sm!100; // 100 cannot be compared to strings using (<)
bad_argument

> smm!"c"; // for stlmmmap, return list of values
[31,32]

> smm!"f"; // stlmmmap returns null list if key is not stored
[]
```

You can access a sequence of elements in an ordered container (stlmap, stlset, stlmmmap or stlmmset) without resorting to iterators using the `next_key` and `prev_key` functions.

**stl::next_key** `acon k`

**stl::prev_key** `acon k`

`acon` must be a stlmap, stlset, stlmmmap or stlmmset. Also if `k` is not `stl::smbeg`, `stl::smend` or an element of `acon` an `out_of_bounds` exception will be throw. `next_key` returns the key of the first element in `acon` that has a key that is greater than `k`. If no such element exists or if `k` is `stl::smbeg`, returns `stl::smend`. `prev_key` returns the last element in `acon` that has a key that is less that `k`, or, if no such element exists, throws an `out_of_bounds` exception.

For various reasons, it is very common to see a call to (!) or `replace` preceded by a call to `member` with the same container and key. E.g.,

```
> bump_wc sm w = if member sm w then replace sm w (sm!w + 1)
  else insert sm (w=>1);
```

In general, this function would require two lookups to add a new word and three lookups to bump the count for an existing word. For the ordered containers, lookups have O(log N) complexity which can be relatively slow for large containers.
To speed things up, each stlmap or stlset maintains a small cache of (key, C++ iterator) pairs for recently accessed keys. During lookup, the cache is checked for a matching key, and if the key is found, the element pointed to by the C++ iterator is used immediately. Thus, when applied to a stlmap or stlset bump_wc will use only one O(log N) search, rather than two or three. For these purposes, a key matches a key in the cache only if it is the same Pure object (i.e., the test is C++ pointer equality, not Pure’s (===) or (==) functions). For example, the following will result in two O(log N) lookups.

```
> if member sm "a" then sm!"a" else insert sm ("a"=>10);
```

Here each “a” is a distinct Pure object. The two “a”s satisfy (==) and even (===) but they are not the same internally and the caching mechanism will not help.

Almost any pure-stlmap function that accepts a stlmap or stlset as an argument will check the container’s cache before doing an O(log N) lookup. Currently the cache is limited to hold only the most recently used key.

Here are some examples produced by compiling pure-stlmap with a trace function that shows caching in action.

```
> let a_key = "a";

> members sm;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]

> member sm a_key; // a_key is not yet in the cache
1

> sm!a_key; // a_key is found in the cache
found iterator for: "a"
1

> replace sm a_key 10;
found iterator for: "a"
10

> sm!"a"; // "a" is a new key, not same C++ pointer as k or a_key
1

> let k = next_key sm a_key; // now k is in the cache, in front of a_key
found iterator for: "a"

> let k1 = next_key sm k; // now k1 is at the head of the queue
found iterator for: "b"

> replace sm k1 30;
found iterator for: "c"
30

> members sm;
["a"=>10,"b"=>2,"c"=>30,"d"=>4,"e"=>5]
```

414 12.8 Container Operations
These examples show that caching can be effective when visiting elements of a stlmap or stlset in order using next_key or prev_key.

### 12.8.5 Conversions

The contents of a pure-stlmap container can be copied to a list, vector, stlvec. For stlmaps, stlsets, stlmmaps and stlmmsets, these operations act on ranges as well as on the entire container.

- **members rng**
  
  Returns a list of the elements in the range, rng.

- **keys rng**
  
  Return the keys and vals of the range’s elements.

- **vals rng**
  
  Return the keys and vals of the range’s elements.

Here are some examples using the members, keys and vals functions.

```plaintext
> members shm; // must do all of shm elements because shm is a stlmap
["d"=>4,"e"=>5,"a"=>1,"b"=>2,"c"=>3]

> keys (sm,"b","e"); // can ask for a range - sm is an ordered container
["b","c","d"]

> vals (sm,"b","e");
[2,3,4]
```

- **stl::vector rng**
  
  Return a vector containing the elements of in the range, rng.

- **stlvec rng**
  
  returns a stlvec containing the elements of in the range, rng.

You can also convert an ordered container (stlmap, stlset, stlmmmap or stlmmset) into a stream of elements.

- **stream rng**
  
  Returns a stream consisting of the range’s elements.

Here is an example using the stream function on a stlmmmap.

```plaintext
> members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4,"e"=>5]

> take 3 $ stream smm;
("a"=>1);#<thunk 0xb70f438c>

> list ans;
["a"=>1,"b"=>2,"c"=>31]
```
12.8.6 Functional Programming

pure-stlmap provides the most commonly used functional programming operations, implemented to act on ranges as if they were lists.

```
# do fun rng
map fun rng
filter pred rng
foldl fun x rng
foldl1 fun rng
foldr fun x rng
foldr1 fun rng
```

These functions are the same as the corresponding functions provided in the Prelude for lists. \texttt{rng} is a rng defined on a stlmap, stlset, stlmmap or stlmset or \texttt{rng} is simply a stlhmap or stlhset. \texttt{foldr} and \texttt{foldr1} are not defined for stlhmaps or stlhsets.

Here are some examples.

```
> members sm;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]
```

```
> map (\(k=>v) -> k+str v) (sm, "b", "e");
["b2", "c3", "d4"]
```

```
> foldl1 (\(k=>v) (ks=>sum) -> (k+ks=>v+sum)) (sm, "b", "e");
"bcd"=>9
```

```
> filter (\(k=>v) -> v mod 2) sm;
["a"=>1,"c"=>3,"e"=>5]
```

```
listmap fun rng
catmap fun rng
rowmap fun rng
rowcatmap fun rng
colmap fun rng
colcatmap fun rng
```

These functions are the same as the corresponding functions provided in the Prelude for lists. \texttt{rng} is a rng defined on a stlmap, stlset, stlmmap or stlmset or simply a stlhmap or stlhset. These functions are provided primarily to enable the use of list and matrix comprehensions over pure-stlmap’s containers. E.g.,

```
> [ k + str v | (k=>v) = (sm, "b", "e")];
["b2", "c3", "d4"]
```

```
> [ k => v | (k=>v) = sm; v mod 2];
["a"=>1,"c"=>3,"e"=>5]
```

```
> { (k;v) | (k=>v) = sm; v mod 2};
{"a", "c", "e"; 1, 3, 5}
```
The functional programming operations work directly on the underlying data structure.

```markdown
> let ints = 0..10000;

stats -m
> filter (==99) ints;
[99]
0s, 6 cells
```

### 12.8.7 Comparison

Two associative containers of the same type are considered to be equal if they contain the same number of elements and if each pair of their corresponding elements are equal. Two elements are equal if their keys are equivalent and, if the container is a stlmap, stlmap or stlhmap, the values associated with equal keys are equal (using the container’s value-equal function).

```markdown
stl::map_equal rng1 rng2
rng1 == rng2
rng1 ~= rng2
```

Test `rng1` and `rng2` for equality or nonequality where `rng1` and `rng2` are ranges defined over containers of the same type.

You need to be careful when using these operators. E.g.,

```markdown
> members ss;
["a","b","c","d","e"]

> let xx = stlset ss;
> xx == ss;
1

> (xx,"a","c") == (ss,"a","c"); // oops!
0
```

The second comparison was intended to compare identical ranges and return true. It failed to do so because (==) is defined in the Prelude to compare tuples element by element, long before it is defined in the stlmap module to compare ranges. The tuple operation take precedence and determines that the tuples are not equal because `xx` and `ss` are different (pointers) for purposes of this comparison. To avoid this issue when using ranges, you can use the `stl::map_equal` function.

```markdown
> map_equal (xx,"a","c") (ss,"a","c");
1
```

The other comparison operators (<), (<=), (>) and (>=) are provided only for the ordered containers (stlmap, stlset, stlmmmap and stlmmset). These operators reflect lexicographical comparisons of keys and, then if the keys are equal, lexicographical comparisons of values. I.e., this is not set inclusion - order matters. Accordingly, these comparison operators are not defined for a stlhmap or stlhset.
rng1 < rng2
Traverse the ranges comparing pairs of elements e1 and e2. If e1 is less than e2, stop and return true; if e2 is less than e1 then stop and return false. If rng1 is exhausted but rng2 is not, return true, else return false. The two ranges must be defined on ordered associative containers of the same type.

rng1 > rng2
rng1 <= rng2
rng1 >= rng2
The these three operators are the same as rng2 < rng1, ~(rng1 >“rng2”) and ~(rng1 <=“rng2) respectively.

You also have to be careful when using equivalence and comparison operators with stlmmaps because elements with the same key and different values are not necessarily ordered by values.

> let smm2 = stlmmap ["a"=>1,"b"=>2,"c"=>32,"c"=>31,"d"=>4];

> members smm;
["a"=>1,"b"=>2,"c"=>31,"c"=>32,"d"=>4]

> members smm2;
["a"=>1,"b"=>2,"c"=>32,"c"=>31,"d"=>4]

> smm == smm2; // probably not what you want
0

These operations do not make much sense for a stlmmap unless elements with equivalent keys are stored by value, in the order enforced by the stlmmap’s value-comp function. In this regard it is worth noting that, depending on your implementation, the insert function may or may not preserve the order of insertion of elements with equivalent keys (C++11 does preserve the order).

12.8.8 Set Algorithms

pure-stlmap provides wrappers for the STL set algorithms that apply to ranges defined on the four ordered associative containers (stlmap, stlset, stlmmap and stlmset). These algorithms are very efficient, with linear time complexity, but they do require that the elements of the two ranges be ordered. Accordingly, the set algorithms are not applicable to stlhmap or stlhset. Also, when dealing with stlmmaps, care must be taken to ensure that items with the equivalent keys are ordered by their values.

stl::map_merge rng1 rng2
Constructs a new ordered container from rng1 and then insert the elements of rng2 into the new container and return it. rng1 and rng2 must be defined on the same type of ordered container.

stl::map_union rng1 rng2
stl::map_difference rng1 rng2
stl::map_intersection rng1 rng2
stl::map_symmetric_difference rng1 rng2
stl::map_includes rng1 rng2

Returns a new ordered associative container of the same type as the ordered containers underlying rng1 and rng2. If the ranges are defined over a stlmap or stlmmmap elements of rng1 have priority over the elements of rng2. Uses rng1’s key-less-than, value-less-than and value-equal functions.

pure-stlmap’s set functions do not necessarily produce the same results as their Pure standard library counterparts. In particular, when applied to multi-keyed containers,

stl::map_union

Produces the multiset union of its arguments while (+) in the Pure standard library produces the multiset sum. If you want the multiset sum of a stlmap or stlmmmap, use stl::map_merge. Also, in pure-stlmap, as in the STL, the left hand map or set has priority of elements while in the Pure standard library the right hand set has priority of elements. This can make a difference when applying set operations to a pair of stlmaps or stlmmmaps. E.g.,

```plaintext
> let smm1 = stlmmmap ["a"=>1,"b"=>2,"c"=>31,"c"=>32];
> let smm2 = stlmmmap ["c"=>32,"c"=>32,"c"=>33,"d"=>4,"e"=>5];

members $ map_merge smm1 smm2; // three "c"=>32
```

```plaintext
> members $ map_union smm1 smm2; // two "c"=>32
```

```plaintext
> let sm1 = stlmap ["a"=>1,"b"=>2,"c"=>31];
> let sm2 = stlmap ["c"=>32,"d"=>4,"e"=>5];

members $ map_union sm1 sm2; // "c"=>31 from sm1, not "c"=>32 from sm2
["a"=>1,"b"=>2,"c"=>31,"d"=>4,"e"=>5]
```

```plaintext
> members $ map_intersection sm1 sm2; // "c"=>31 from sm1
["c"=>31]
```

12.8.9 Direct C Calls

It is common to encounter code that (a) tests if a key is stored in a container using member and (b) in the case of maps, retrieves the value or values associated with the key using (!) and/or (c) changes the value or values using replace. Depending on what modules have been loaded, these functions may be heavily overloaded which can cause a small delay when the functions are called. To avoid this, pure-stlmap exposes the corresponding C functions so that they can be called directly. The C functions have the same name as the overloaded functions except for a prefix. E.g.,

```plaintext
stl::sm_member(sm_key, sm_key)
stl::sm_get(sm_key, sm_key)
stl::sm_put(sm_key, sm_key, val)
```

The first two functions are the direct C call equivalents of (::member sm_key) and (sm1(key)). The third is like (::replace sm_key, val) except that it will insert (key=>val) if key is not already stored in sm. Here, sm is a stlmap or a stlset (except that sm_put is not defined for stlsets).
stl::shm_member shm key
stl::shm_get shm key
stl::shm_put shm key val

The first two functions are the direct C call equivalents of (::member shm key) and (shm!key). The third is like (::replace shm key val) except that it will insert (key=>val) if key is not already stored in shm. Here, shm is a stl_map or a stl_set (except that shm_put is not defined for stl_sets).

stl::smm_member smm key
stl::smm_get smm key
stl::smm_put smm key vals

The first two functions are the direct C call equivalents of (::member smm key) and (smm!key). The third is like (::replace smm key val) except that it will insert (key=>val1, key=>val2, ...) if key is not already stored in smm. Here, smm is a stl_map or a stl_set (except that smm_put is not defined for stl_sets).

12.9 Iterators

This section provides a quick overview of pure-stl_map’s “iterator-based” interface.

12.9.1 Concepts

Given a valid iterator you can access, modify or erase the element it points to.

```plaintext
> let sm1 = stl_map sm; members sm1;
{"a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5};

> let i = find sm1 "b";  // use find to get an iterator - like C++

> get_elm i;
"b"=>2

> get_val i;
2

> put_val i 20;
20

> members sm1;
{"a"=>1,"b"=>20,"c"=>3,"d"=>4,"e"=>5}
```

Please note that you can never modify an element’s key, only its value. If you want to change both key and value, you have to erase the element and insert a new element.

```plaintext
> erase (sm1,i) $$ insert sm1 ("bl"=>21);
1

> members sm1;
{"a"=>1,"bl"=>21,"c"=>3,"d"=>4,"e"=>5}
```
Given two iterators, i and j, pointing into a ordered container oc, the range (i,j), denotes oc's elements starting with “oc[i]”, the element pointed to by i, up to but not including oc[j]. In pure-stlmap, this range is denoted by the tuple (i,j).

> members sm;
["a"=>1,"b"=>2,"c"=>3,"d"=>4,"e"=>5]

> let i = stl::find sm1 "b"; // get the iterator
> let j = stl::find sm1 "e";

> members (i,j); // get the elements in the range
["b"=>2,"c"=>3,"d"=>4]

Perhaps it is worth mentioning that functions that act on ranges do not care if the range is specified by a pair of iterators or by keys.

> members ss;
["a","b","c","d","e"]

> map (+21) (ss,"c",smend);
["x","y","z"]

> let i = find ss "c";
> let j = pastend ss;
> map (+21) (i,j);
["x","y","z"]

### 12.9.2 Exceptions

In pure-stlmap functions that accept iterators throw a bad_argument exception if called with an invalid iterator. An iterator remains valid until the element it was pointing to has been erased. These functions also attempt to throw bad argument exceptions for invalid usage that would otherwise result in undefined behavior. An example of an invalid use would be a range specified by iterators from different containers. Here are some examples of iterator errors.

> let i,j = find sm "a", find sm "d";

> get_elm i, get_elm j;
"a"=>1,"d"=>4

> members (i,j);
["a"=>1,"b"=>2,"c"=>3]

> catch id $ members (j,i); // j and i transposed, C++ would segfault
bad_argument

> erase (sm,"b"); // erase "b"=>2, leaving i and j valid
1

> get_elm i; // still valid

### 12.9.2 Exceptions
"a"=>1

> erase (sm,"a"); // erase "a"=>1 - invalidating i
1

> catch id $ get_elm i; // bad iterator exception
bad_argument

12.9.3 Functions

In this section “acon” always denotes one of the containers that supports interitors (stlmap, stlset, stlmmmap and stlmset).

stl::iterator i
Returns a new iterator that points to the same element as i.

stl::begin acon
stl::pastend acon
Returns acon’s begin or past-end iterator.

stl::find acon k
Creates a new iterator that points to an element in acon with key equivalent to k (if any) or acon’s past-end iterator if no such element exists.

stl::find_with_default map k
Returns an iterator pointing to the element in map, a stlmap, with key equivalent to k. If no such element existed before the call, one is created and inserted using k and map’s default value. This function is pure-stlmap’s version of C++’s [] operator for associative containers.

stl::insert_elm acon elm
Attempts to insert elm into acon. (If acon is a stlmap or stlmmmap, then elm must be a key value pair, (k=>v)). If acon is a stlmap or stlset (i.e., with unique keys) insert_elm returns a pair, the first of which is an iterator pointing to the element with key k that was just inserted (or the pre-existing element that blocked the insertion). The second element in the pair is a boolean value that is true if a new element was inserted. In contrast, if acon is a multi-keyed container (stlmmmap or stlmset) the insert will always be successful and insert_elm returns an iterator pointing to the element with key k that was just inserted, instead of an (iterator, boolean) tuple.

stl::insert_elm acon (elm,i)
This is the same as the previous function except that (a) i is passed in as a hint to where the new element should be inserted and (b) a single iterator is returned rather than a iterator,boolean pair. If the new element is inserted just after i, the insertion can have constant time complexity.

stl::l_bound acon k
Return a new iterator that points to the first element in acon, a stlmap, stlset, stlmmmap or stlmset, that is not less than k, or acon’s past-end iterator if none exists.
stl::u_bound acon k
   Return a new iterator that points to the first element in acon, a stlmap, stlset, stlmmap or stlmset, that is greater than k, or acon’s past-end iterator if none exists.

stl::lu_bounds acon k
   Return the pair l_bound k, u_bound k.

E.g.,
> let ok, smx, f, l = stl::range_info (sm1,"b","e");
> ok, smx === sm1, stl::members (f,l);
1,1,"b"=>2,"c"=>3,"d"=>4

stl::inc i
stl::dec i
stl::move i n::int
   Move the iterator i forward one, back one or forward n elements respectively, where n can be negative. The iterator is mutated by these operations, provided the move is successful. An attempt to move to a position before the first element’s position causes an out_of_bounds exception. Moves past the last element return the past-end iterator for the container that i is defined on.

stl::get_elm i
stl::get_key i
stl::get_val i
   Return the element pointed to by the iterator i, or the element’s key or value. For maps the element is returned as a key=>value hash rocket pair. For sets, get_elem, get_key and get_val all return the element (which is the same as its key).

stl::put_val i newvalue
   Change the value of the element pointed to by the iterator i to newvalue. The element’s key cannot be changed. The iterator must point into a stlmap or stlmmap.

stl::begin i
stl::pastend i
   Returns true if the iterator i is the begin iterator or pastend iterator of the container it is defined on.

stl::get_info i
   Returns a tuple (is_valid,acon,key,val) where is_valid is true if the iterator i is valid or false if not, acon is the container that i is defined on, and key, val are the key and value of the element i points to, if any. If i is the past-end iterator, key and val are set to stl::smend and [], respectively.

i==j
   Returns true if the iterators i and j point to the same element.

erase (acon,i)
erase (acon,i,j)
   Erases the element pointed to by i or the elements in the range (i, j). Both i and j must be iterators defined on acon (or a bad_argument exception will be thrown).
12.9.4 Examples

Here are some examples using iterators.

```plaintext
> let b, e = begin smm, pastend smm;

> members (b, e);
["a"=>1, "b"=>2, "c"=>31, "c"=>32, "d"=>4, "e"=>5]

> let i, j = lu_bounds smm "c";

> members (b, i);
["a"=>1, "b"=>2]

> members (i, j);
["c"=>31, "c"=>32]

> members (j, e);
["d"=>4, "e"=>5]

> get_elm i;
"c"=>31

> get_elm (inc i);
"c"=>32

> put_val i 132;
132

> map (\(k=>_)->k=>ord k) (b, i);
["a"=>97, "b"=>98, "c"=>99]

> let is_set, smm1, k, v = get_info i; is_set, members smm1, k, v;
1, ["a"=>1, "b"=>2, "c"=>31, "c"=>132, "d"=>4, "e"=>5], "c", 132

> get_elm (dec j);
"c"=>132

> inc j $$ inc j $$ get_elm j;
"e"=>5

> inc j $$ endp j;
1
```

12.10 Backward Compatibilty

This section documents changes in pure-stlmap.

12.10.1 pure-stlmap-0.2

Optimized common predicates, such as (<) and (>)
12.10.2  pure-stlmap-0.3

Fixed (>) comparisons on plain old data.
Chapter 13

pure-stlvec

Version 0.4, April 11, 2018

Peter Summerland <p.summerland@gmail.com>

Pure’s interface to C++ vectors, specialized to hold pointers to arbitrary Pure expressions, and the C++ Standard Template Library algorithms that act on them.

13.1 Copying

Copyright (c) 2011 by Peter Summerland <p.summerland@gmail.com>.

All rights reserved.

pure-stlvec is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

pure-stlvec is distributed under a BSD-style license, see the COPYING file for details.

13.2 Installation

pure-stlvec-0.4 is included in the “umbrella” addon, pure-stllib, which is available at https://bitbucket.org/purelang/pure-lang/downloads. After you have downloaded and installed pure-stllib, you will be able to use pure-stlvec (and pure-stlmap, as well).
13.3 Overview

The C++ Standard Template Library ("STL") is a library of generic containers (data structures designed for storing other objects) and a rich set of generic algorithms that operate on them. pure-stlvec provides an interface to one of its most useful containers, “vector”, adopted to hold pointers to Pure expressions. The interface provides Pure programmers with a mutable container “stlvec”, that, like the STL’s vector, holds a sequence of objects that can be accessed in constant time according to their position in the sequence.

13.3.1 Modules

The usual operations for creating, accessing and modifying stlvecs are provided by the stlvec module. Most of the operations are similar in name and function to those provided by the Pure Library for other containers. As is the case for their Pure Library counterparts, these operations are in the global namespace. There are a few operations that have been placed in the stl namespace usually because they do not have Pure Library counterparts.

In addition to the stlvec module, pure-stlvec provides a group of modules, stlvec::modifying, stlvec::nonmodifying, stlvec::sort, stlvec::merge, stlvec::heap, stlvec::minmax and stlvec::numeric, that are straight wrappers the STL algorithms (specialized to work with STL vectors of pointers to Pure expressions). This grouping of the STL algorithms follows that found at http://www.cplusplus.com/reference/algorithm/. This web page contains a table that summarizes of all of the algorithms in one place.

pure-stlvec provides an “umbrella” module, stlvec::algorithms, that pulls in all of the STL algorithm interface modules in one go. The STL algorithm wrapper functions reside in the stl namespace and have the same names as their counterparts in the STL.

13.3.2 Simple Examples

Here are some examples that use the basic operations provided by the stlvec module.

```
> using stlvec;

> let sv1 = stlvec (0..4); members sv1;
[0,1,2,3,4]

> insert (sv1,stl::svend) (5..7); members sv1;
STLVEC #<pointer 0xaf4d2c0>
[0,1,2,3,4,5,6,7]

> sv1!3;
3

> sv1!![2,4,6];
[2,4,6]

> replace sv1 3 33; members sv1;
STLVEC #<pointer 0xaf4d4d2c0>
[0,1,2,33,4,5,6,7]
```
Here are some examples that use STL algorithms.

```cpp
> using stlvec::algorithms;

> stl::reverse (sv1,2,6); members sv1;
STLVEC #<pointer 0xaf4d2c0>
[0,1,5,4,3,2,6,7]

> stl::stable_sort sv1 (>); members sv1;
()  
[7,6,5,4,3,2,1,0]

> stl::random_shuffle sv1; members sv1 1;
()  
[1,3,5,4,0,7,6,2]

> stl::partition sv1 (<3); members (sv1,0,ans); members sv1;
3  
[1,2,0]
[1,2,0,4,5,7,6,3]

13.3.2 Simple Examples
> std::transform sv1 (sv1,0) (*2); members sv1;
> [2,4,0,8,10,14,12,6]
> let sv2 = emptystlvec;
> std::transform sv1 (sv2, std::svback) (div 2); members sv2;
> [1,2,0,4,5,7,6,3]

Many more examples can be found in the pure-stlvec/ut directory.

13.3.3 Members and Sequences of Members

Throughout the documentation for pure-stlvec, the member of a stlvec that is at the nth position in the sequence of expressions stored in the stlvec is referred to as its nth member or nth element. The nth member of a stlvec, sv, is sometimes denoted by sv\[n. The sequence of members of sv starting at position i up to but not including j is denoted by sv\[i\,j). There is a "past-the-end" symbol, std::svend, that denotes the position after that occupied by the last member contained by a stlvec.

For example, if sv contains the sequence "a", "b", "c" "d" and "e", sv\[0) is "a", sv\[1,3) is the sequence consisting of "b" followed by "c" and v\[3, std::svend) denotes the sequence consisting of "d" followed by "e".

13.3.4 STL Iterators and Value Semantics

In C++ a programmer accesses a STL container’s elements by means of “iterators”, which can be thought of as pointers to the container’s elements. A single iterator can be used to access a specific element, and a pair of iterators can be used to access a “range” of elements. By convention, such a range includes the member pointed to by the first iterator and all succeeding members up to but not including the member pointed to by the second iterator. Each container has a past-the-end iterator that can be used to specify ranges that include the container’s last member.

In the case of vectors there is an obvious correspondence between an iterator that points to an element and the element’s position (starting at zero) in the vector. pure-stlvec uses this correspondence to designate a stlvec’s members in a way that makes it relatively easy to see how pure-stlvec’s functions are acting on the stlvec’s underlying STL vector by referencing the STL’s documentation. Thus, if sv is a stlvec, and j is an int, “replace sv j x” uses the STL to replace the element pointed to by the iterator for position j of sv’s underlying STL vector. If, in addition, k is an int, std::sort (sv, j, k) (<) uses the STL to sort the elements in the range designated by the “jth” and “kth” iterators for sv’s underlying STL vector. This range, written as sv\[j,k), is the subsequence of sv that begins with the element at position j and ends with the element at position (k-1).

Besides iterators, another cornerstone of the STL is its “value semantics”, i.e., all of the STL containers are mutable and if a container is copied, all of its elements are copied. pure-stlvec
deals with the STL’s value semantics by introducing mutable and nonmutable stlvecs, and by storing smart pointers to objects (which have cheap copies) rather than the actual objects.

13.3.5 Iterator Tuples

As mentioned in the previous section, in C++ ranges are specified by a pair of STL iterators. In pure-stlvec ranges of elements in a stlvec are specified by “iterator tuples” rather than, say, actual pointers to STL iterators. Iterator tuples consist of the name of a stlvec followed by one or more ints that indicate positions (starting from zero) of the stlvec’s elements.

To illustrate how iterator tuples are used, consider the STL stable_sort function, which sorts objects in the range \([\text{first}, \text{last})\) in the order imposed by \(\text{comp}\). Its C++ signature looks like this:

```c++
void stable_sort ( RandomAccessIterator first, RandomAccessIterator last, Compare comp )
```

The corresponding pure-stlvec function, from the stlvec::sort module, looks like this:

```c++
stable_sort (msv, first, last) comp
```

where \(\text{msv}\) is a mutable stlvec, and \(\text{first}\) and \(\text{last}\) are ints. The first thing that the Pure stable_sort does is create a pair of C++ iterators that point to the elements in \(\text{msv}\)’s underlying STL vector that occupy the positions designated by \(\text{first}\) and \(\text{last}\). Next it wraps the Pure comp function in a C++ function object that, along with the two iterators, is passed to the C++ stable_sort function.

For convenience, \((\text{sv},\text{stl::svbeg, stl::svend})\) can be written simply as \(\text{sv}\). Thus, if \(\text{first}\) were \(\text{stl::svbeg}\) (or 0), and \(\text{last}\) were \(\text{stl::svend}\) (or \(\#\text{msv}\), the number of elements in \(\text{msv}\)), the last Pure call could be written:

```c++
stable_sort msv comp
```

It should be noted that often the STL library provides a default version of its functions, which like stable_sort, use a comparator or other callback function provided by the caller. E.g., the C++ stable_sort has a default version that assumes the “\(<\)” operator can be used on the elements held by the container in question:

```c++
void stable_sort ( RandomAccessIterator first, RandomAccessIterator last)
```

The corresponding functions provided by the pure-stlvec modules rarely, if ever, supply a default version. A typical example is stlvec::sort’s stable_sort which must be called with a comparator callback function:

```c++
stable_sort msv (<);
```

Note also that the comparator (e.g., (<)), or other function being passed to a pure-stlvec algorithm wrapper is almost always the last parameter. This is the opposite of what is required for similar Pure functions, but is consistent with the STL calling conventions.

13.3.6 Predefined Iterator Tuple Indexes

The following integer constants are defined in the stl namespace for use in iterator tuples.
constant stl::svbeg = 0
constant stl::svend = -1
constant stl::svback = -2

These three symbols are declared as nonfix. svend corresponds to STL’s past-end iterator for
STL vectors. It makes it possible to specify ranges that include the last element of an stlvec.
I.e., the iterator tuple (sv,stl::svbeg,stl::svend) would specify sv[0,n), where n is the number
of elements in sv. In order to understand the purpose of svback, it is necessary to understand
a bit about STL’s “back insert iterators.”

13.3.7 Back Insert Iterators

Many of the STL algorithms insert members into a target range designated by an iterator
that points to the first member of the target range. Consistent with raw C usage, it is ok to
copy over existing elements the target stlvec. E.g.,

> using stlvec::modifying;
> let v1 = stlvec (0..2);
> let v2 = stlvec ("a".."g");
> stl::copy v1 (v2,2) $$ members v2;
["a","b",0,1,2,"f","g"]

This is great for C++ programmers, but for Pure programmers it is almost always preferable
to append the copied items to the end of a target stlvec, rather than overwriting all or part
or part of it. This can be accomplished using stl::svback. E.g.,

> stl::copy v1 (v2,stl::svback) $$ members v2;
["a","b",0,1,2,"f","g",0,1,2]

In short, when a pure-stlvec function detects “stl::svback” in a target iterator tuple, it con-
structs a STL “back inserter iterator” and passes it on to the corresponding wrapped STL
function.

13.3.8 Data Structure

Currently, stlvecs are of the form (STLVEC x) or (CONST_STLVEC x), where STLVEC AND
CONST_STLVEC are defined as nonfix symbols in the global namespace and x is a pointer
to the underlying STL vector. The stlvec module defines corresponding type tags, stlvec and
const_stlvec, so the programmer never needs to worry about the underlying representaton.

This representation may change in the future, and must not be relied upon by client modules.
In particular, one must never attempt to use the embedded pointer directly.

As the names suggest, stlvecs are mutable and const_stlvecs are immutable. Functions that
modify a stlvec will simply fail unless the stlvec is mutable.

> let v = const_stlvec $ stlvec (0..3); v2;
CONST_STLVEC #<pointer 0x8c1dbf0>
13.3.9 Types

pure-stlvec introduces six type tags, all of which are in the global namespace:

- **type mutable_stlvec**
  The type for a mutable stlvec.

- **type const_stlvec**
  The type for an immutable stlvec.

- **type stlvec**
  The type for a stlvec, mutable or immutable.

- **type mutable_svit**
  The type for an iterator tuple whose underlying stlvec is mutable.

- **type const_svit**
  The type for an iterator tuple whose underlying stlvec is immutable.

- **type svit**
  The type for an iterator tuple. The underlying stlvec can be mutable or immutable.

13.3.10 Copy-On-Write Semantics

The pure-stlvec module functions do not implement automatic copy-on-write semantics. Functions that modify stlvec parameters will simply fail if they are passed a const_stlvec when they expect a mutable_stlvec.

For those that prefer immutable data structures, stlvecs can be converted to const_stlvecs (usually after they have been created and modified within a function) by the const_stlvec function. This function converts a mutable stlvec to an immutable stlvec without changing the underlying STL vector.

Typically, a “pure” function that “modifies” a stlvec passed to it as an argument will first copy the input stlvec to a new locally scoped (mutable) stlvec using the stlvec function. It will then modify the new stlvec and use const_stlvec to make the new stlvec immutable before it is returned. It should be noted that several of the STL algorithms have “copy” versions which place their results directly into a new stlvec, which can eliminate the need to copy the input stlvec. E.g.:

```pure
> let sv1 = stlvec ("a"..'e");
> let sv2 = emptystlvec;
> stl::reverse_copy sv1 (sv2, stl::svback) $$ members sv2;
["e","d","c","b","a"]
```

Without reverse_copy, one would have had to copy sv1 into sv2 and then reverse sv2.

---

> replace v 0 100; // fails
replace (CONST_STLVEC #<pointer 0x9f07690> 0 100)
If desired, in Pure it is easy to write functions that have automatic copy-on-write semantics. E.g.,

> my_replace csv::const_stlvec i x = my_replace (stlvec csv) i x;
> my_replace sv::stlvec i x = replace sv i x;

### 13.3.11 Documentation

The pure-stllib/doc directory includes a rudimentary cheatsheet, pure-stllib-cheatsheet.pdf, that shows the signatures of all of the functions provided by pure-stlvec (and by pure-stlmap as well).

The documentation of the functions provided by the stlvec module are reasonably complete. In contrast, the descriptions of functions provided by the STL algorithm modules are purposely simplified (and may not, therefore, be technically accurate). This reflects that fact that the functions provided by pure-stlvec have an obvious correspondence to the functions provided by the STL, and the STL is extremely well documented. Furthermore, using the Pure interpreter, it is very easy to simply play around with any of the pure-stlvec functions if there are doubts, especially with respect to “corner cases.” Often this leads to a deeper understanding compared to reading a precise technical description.

### 13.3.12 Parameter Names

In the descriptions of functions that follow, parameter names used in function descriptions represent specific types of Pure objects:

- **sv** stlvec (mutable or immutable)
- **csv** const (i.e., immutable) stlvec
- **msv** mutable stlvec
- **x** an arbitrary Pure expression
- **xs** a list of arbitrary Pure expressions
- **count, sz, n** whole numbers to indicate a number of elements, size of a vector, etc
- **i, j** whole numbers used to designate indexes into a stlvec
- **f, m, l** whole numbers (or stl::beg or stl::svend) designating the “first”, “middle” or “last” iterators in a stlvec iterator tuple
- **p** a whole number (or other iterator constant such as stl::svend or stl::svback) used in a two element iterator tuple (e.g., (sv, p))
- **(sv, p)** an iterator tuple that will be mapped to an iterator that points to the pth position of sv’s underlying STL vector, v, (or to a back iterator on v if p is stl::svback)
(sv,f,l) an iterator tuple that will be mapped to the pair of iterators that are designated by (sv,f) and (sv,l)

(sv,f,m,l) an iterator tuple that will be mapped to the iterators that are designated by (sv,f), (sv,m) and (sv,l)

sv[f,l) the range of members beginning with that at (sv,f) up to but not including that at (con,l)

comp a function that accepts two objects and returns true if the first argument is less than the second (in the strict weak ordering defined by comp), and false otherwise

unary_pred a function that accepts one object and returns true or false

bin_pred a function that accepts two objects and returns true or false

unary_fun a function that accepts one objects and returns another

bin_fun a function that accepts two objects and returns another

gen_fun a function of one parameter that produces a sequence of objects, one for each call

For readability, and to correspond with the STL documentation, the words “first”, “middle”, and “last”, or variants such as “firstl” are often used instead of f,m,l.

13.4 Error Handling

The functions provided this module handle errors by throwing exceptions.

13.4.1 Exception Symbols

constructor bad_argument
This exception is thrown when a function is passed an unexpected value. A subtle error to watch for is a malformed iterator tuple (e.g., one with the wrong number of elements).

constructor bad_function
This exception is thrown when a purported Pure call-back function is not even callable.

constructor failed_cond
This exception is thrown when a Pure call-back predicate returns a value that is not an int.

constructor out_of_bounds
This exception is thrown if the specified index is out of bounds.

constructor range_overflow
This exception is thrown by functions that write over part of a target stlvec (e.g., copy) when the target range too small to accommodate the result.

constructor range_overlap
This exception is thrown by algorithm functions that write over part of a target stlvec when the target and source ranges overlap in a way that is not allowed.
In addition, any exception thrown by a Pure callback function passed to a pure-stlvec function will be caught and be rethrown by the pure-stlvec function.

13.4.2 Examples

> using stlvec, stlvec::modifying;

> let sv1 = stlvec (0..4); members sv1;
[0,1,2,3,4]

> let sv2 = stlvec ("a".."e"); members sv2;
["a","b","c","d","e"]

> sv1!10;
<stdin>, line 25: unhandled exception ‘out_of_bounds’ ...

> stl::copy sv1 (sv2,10);
<stdin>, line 26: unhandled exception ‘out_of_bounds’ ...

> stl::copy sv1 (sv2,2,3); // sb (sv2,pos)
<stdin>, line 22: unhandled exception ‘bad_argument’ ...

> stl::copy sv1 (sv2,2);
<stdin>, line 23: unhandled exception ‘range_overflow’ ...

> stl::copy sv2 (sv2,2);
<stdin>, line 24: unhandled exception ‘range_overlap’ ...

> stl::copy (sv1,1,3) (sv2,0); members sv2; // ok
2
[1,2,"c","d","e"]

> stl::sort sv2 (>); // apples and oranges
<stdin>, line 31: unhandled exception ‘failed_cond’

> listmap (\x->throw DOA) sv1; // callback function throws exception
<stdin>, line 34: unhandled exception ‘DOA’ ...

13.5 Operations Included in the stlvec Module

The stlvec module provides functions for creating, accessing and modifying stlvecs. In general, operations that have the same name as a corresponding function in the Pure standard library are in the global namespace. The remaining functions, which are usually specific to stlvecs, are in the stl namespace.

Please note that “stlvec to stlvec” functions are provided by the pure-stl algorithm modules. Thus, for example, the stlvec module does not provide a function that maps one stlvec onto a new stlvec. That functionality, and more, is provided by stl::transform, which can be found in the stlvec::modifying module.
13.5.1 Imports

To use the operations of this module, add the following import declaration to your program:

```
using stlvec;
```

13.5.2 Operations in the Global Namespace

When reading the function descriptions that follow, please bear in mind that whenever a function is passed an iterator tuple of the form (sv,first, last), first and last can be dropped, leaving (sv), or simply sv. The function will treat the “unary” iterator tuple (sv) as (sv, std::svbeg, std::svend).

**emptystlvec**

return an empty stlvec

**stlvec source /stlvec**

create a new stlvec that contains the elements of source; source can be a stlvec, an iterator tuple(sv,first,last), a list or a vector (i.e., a matrix consisting of a single row or column). The underlying STL vector is always a new STL vector. I.e., if source is a stlvec the new stlvec does not share source’s underlying STL vector.

**mkstlvec** x count

create a new stlvec consisting of count x’s.

**const_stlvec source**

create a new const_stlvec that contains the elements of source; source can be a stlvec, an iterator tuple(sv,first,last), a list or a vector (i.e., a matrix consisting of a single row or column). If source is a stlvec (mutable or const), the new const_stlvec shares source’s underlying STL vector.

**# sv**

return the number of elements in sv.

Note that # applied to an iterator tuple like (sv,b,e) will just return the number of elements in the tuple. Use stl::bounds if you need to know the number of elements in the range denoted by an iterator tuple.

**sv ! i**

return the ith member of sv

Note that !k applied to an iterator tuple like (sv,b,e) will just return the kth element of the tuple. In addition, in stlvec, integers used to denote positions (as in ‘k) or in iterators, always, are relative to the beginning of the underlying vector. So it makes no sense to apply ! to an iterator tuple.

**first sv**

**last sv**

first and last member of sv

**members** (sv, first, last)

return a list of values stored in sv[first, last)
**replace** msv i x
   replace the ith member of msv by x and return x; throws out_of_bounds if i is less than
   0 or great or equal to the number of elements in msv

**update** msv i x
   the same as replace except that update returns msv instead of x. This function is DEP-
   RECATED.

**append** sv x
   append x to the end of sv

**insert** (msv,p) xs

**insert** (msv,p) (sv,first,last)
   insert members of the list xs or the range sv[first, last) into msv, all preceding the pth
   member of msv. Members are shifted to make room for the inserted members

**rmove** msv

**rmlast** msv
   remove the first or last member from msv

**erase** (msv,first,last)

**erase** (msv,p)

**erase** msv
   remove msv[first,last) from msv, remove msv\'p from msv, or make msv empty. Mem-
   bers are shifted to occupy vacated slots

sv1 == sv2
sv1 ~= sv2
   (x == y) is the same as stl::allpairs (==) x y and x ~= y is simply ~(allpairs (==) x y)

Note that == and ~= are not defined for iterator tuples (the rules would never be executed
because == is defined on tuples in the Prelude).

The stlvec module provides convenience functions that apply map, catmap, foldl, etc, to
directly access Pure expressions stored in a stlvec.

**map** unary_fun (sv, first, last)
   one pass equivalent of map unary_fun $ members (sv, first, last)

**listmap** unary_fun (sv, first, last)
   same as map, used in list comprehensions

**catmap** unary_fun (sv, first, last)
   one pass equivalent of catmap unary_fun $ members (sv, first, last)

**do** unary_fun (sv, first, last)
   one pass equivalent of do unary_fun $ members (sv, first, last)

**foldl** bin_fun x (sv, first, last)
   one pass equivalent of foldl bin_fun x $ members (sv, first, last)

**foldl1** bin_fun (sv, first, last)
   one pass equivalent of foldl1 bin_fun $ members (sv, first, last)
filter unary_pred (sv, first, last)
    one pass equivalent of filter unary_pred $ members (sv, first, last)

The following four functions map (or catmap) stlvecs onto row and col matrixes, primarily
for use in matrix comprehensions.

rowmap unary_fun (sv, first, last)
rowcatmap unary_fun (sv, first, last)
colmap unary_fun (sv, first, last)
colcatmap unary_fun (sv, first, last)

13.5.3 Operations in the stl Namespace

stl::empty sv
    test whether sv is empty

stl::vector (sv,first,last)
    create a Pure vector that contains the members of sv[first,last)

stl::allpairs bin_pred (sv1, first1, last1) (sv2, first2, last2)
    returns true if bin_pred is true for all corresponding members of sv1[first1, last1) and
    sv2[first2, last2)

stl::bounds (sv,first,last)
    throws out-of-bounds if first or last is out of bounds. returns the tuple (sv,first,last)
    except that if first is stl::begin it will be replaced by 0 and if last is stl::svend it will be
    replaced by the number of elements in sv.

stl::reserve msv count
    modify the underlying STL vector to have at least count slots, useful for packing data
    into a fixed size vector and possibly to speed up the addition of new members

stl::capacity sv
    return the number of slots (as opposed to the number of elements) held by the under-
    lying STL vector

13.5.4 Examples

See ut_stlvec.pure and ut_global_stlvec.pure in the pure-stlvec/ut directory.

13.6 STL Nonmodifying Algorithms

The stlvec::nonmodifying module provides an interface to the STL’s non-modifying se-
quence operations.

13.6.1 Imports

To use the operations of this module, add the following import declaration to your program:
using stlvec::nonmodifying;

All of the functions are in the stl namespace.

13.6.2 Operations

stl::for_each (sv, first, last) unary_fun
applies unary_fun to each of the elements in sv[first, last)

stl::find (sv, first, last) x
returns the position of the first element in sv[first, last) for which (==x) is true (or stl::svend if not found)

stl::find_if (sv, first, last) unary_pred
returns the position of the first element in sv[first, last) for which unary_pred is true (or stl::svend if not found)

stl::find_first_of (sv1, first1, last1) (sv2, first2, last2) bin_pred
Returns the position of the first element, x, in sv1[first1, last1) for which there exists y in sv2[first2, last2) and (bin_pred x y) is true (or stl::svend if no such x exists).

stl::adjacent_find (sv, first, last) bin_pred
search sv[first, last) for the first occurrence of two consecutive elements (x, y) for which (bin_pred x y) is true. Returns the position of x, if found, or stl::svend if not found)

stl::count (sv, first, last) x
returns the number of elements in the range sv[first, last) for which (x==) is true

stl::count_if (sv, first, last) unary_pred
returns the number of elements in the range sv[first, last) for which unary_pred is true

stl::mismatch (sv1, first1, last1) (sv2, first2) bin_pred
applies bin_pred pairwise to the elements of sv1[first1, last1) and (sv2, first2, first2 + n), with n equal to last1-first1 until it finds i and j such that bin_pred (sv1!i) (sv2!j) is false and returns (i, j). If bin_pred is true for all of the pairs of elements, i will be stl::svend and j will be first2 + n (or stl::svend)

stl::equal (sv1, first1, last1) (sv2, first2) bin_pred
applies bin_pred pairwise to the elements of sv1[first1, last1) and (sv2, first2, first2 + n), with n equal to last1-first1, and returns true if bin_pred is true for each pair

stl::search (sv1, first1, last1) (sv2, first2) bin_pred
using bin_pred to determine equality of the elements, searches sv1[first1, last1) for the first occurrence of the sequence defined by sv2[first2, last2), and returns the position in sv1 of its first element (or stl::svend if not found)

stl::search_n (sv, first, last) count x bin_pred
using bin_pred to determine equality of the elements, searches sv[first, last) for a sequence of count elements that equal x. If such a sequence is found, it returns the position of the first of its elements, otherwise it returns stl::svend
stl::find_end (sv1, first1, last1) (sv2, first2, last2) bin_pred
using bin_pred to determine equality of the elements, searches sv1[first1,last1) for the last occurrence of sv2[first2,last2). Returns the position of the first element in sv1 of the occurrence (or stl::svend if not found).

13.6.3 Examples
See ut_nonmodifying.pure in the pure-stlvec/ut directory.

13.7 STL Modifying Algorithms
The stlvec::modifying module provides an interface to the STL’s modifying algorithms.

13.7.1 Imports
To use the operations of this module, add the following import declaration to your program:
using stlvec::modifying;

All of the functions are in the stl namespace.

13.7.2 Operations
stl::copy (sv, first1, last1) (msv, first2)
copies the elements in sv[first1,last1) into the range whose first element is (msv,first2)

stl::copy_backward (sv,first1,last1) (msv,last2)
copies the elements in sv[first1,last1), moving backward from (last1), into the range msv[first2,last2) where first2 is last2 minus the number of elements in sv[first1,last1)

stl::swap_ranges (sv,first,last) (msv, p)
exchanges the elements in sv[first, last) with those in msv[p, p+n) where n is last - first

stl::transform (sv,first,last) (msv, p) unary_fun
applies unary_fun to the elements of sv[first,last) and places the resulting sequence in msv[p, p+n) where n is last - first. If sv is mutable, msv and sv can be the same stlvec. Returns (msv,p+n)

stl::transform_2 (sv1,first1,last1) (sv2,first2) (msv, p) bin_fun
applies bin_fun to corresponding pairs of elements of sv1[first1,last1) sv2[first2,n) and and places the resulting sequence in msv[p, p+n) where n is last1 - first1. Returns (msv,p+n)

stl::replace_if (msv,first,last) unary_pred x
replace the elements of msv[first,last) that satistfy unary_pred with x

stl::replace_copy (sv,first,last) (msv,p) x y
same as replace (msv,first,last) x y except that the modified sequence is placed in msv[p,p+last-first)
stl::replace_copy_if (sv,first,last) (msv,p) unary_pred x
   same as replace_if except that the modified sequence is placed in msv[p,p+last-first)

stl::fill (msv,first,last) x
   replace all elements in msv[first,last) with x

stl::fill_n (msv,first) n x
   replace the elements of msv[first,first+n) with x

stl::generate (msv,first,last) gen_fun
   replace the elements in msv[first,last) with the sequence generated by successive calls to gen_fun (), e.g.,
   > let count = ref 0;
   > let g _ = n when n = get count + 1; put count n; end;
   > let sv = mkstlvec 0 10;
   > stl::generate sv g $$ members sv;
   [1,2,3,4,5,6,7,8,9,10]

stl::generate_n (msv,first) n gen_fun
   replace all elements in msv[first,first+n) with the sequence generated by successive calls to gen_fun

stl::remove (msv,first,last) x
   same as remove_if (msv,first,last) (==x).

stl::remove_if (msv,first,last) unary_pred
   remove elements in msv[first,last) that satisfy unary_pred. If n elements do not satisfy unary_pred, they are moved to msv[first,first+n), preserving their relative order. The content of msv[first+n,svend) is undefined. Returns first+n, or stl::svend if first+n is greater than the number of elements in msv

stl::remove_copy (sv,first,last) (msv,first) x
   same as remove except that the purged sequence is copied to (msv,first) and sv[first,last) is not changed

stl::remove_copy_if (sv,first,last) (msv,first) unary_pred
   same as remove_if except that the purged sequence is copied to (msv,first) and sv[first,last) is not changed

stl::unique (msv,first,last) bin_pred
   eliminates consecutive duplicates from sv[first,last), using bin_pred to test for equality. The purged sequence is moved to sv[first,first+n) preserving their relative order, where n is the size of the purged sequence. Returns first+n or stl::svend if first+n is greater than the number of elements in msv

stl::unique_copy (sv,first,last) (msv,first) bin_pred
   same as unique except that the purged sequence is copied to (msv,first) and sv[first,last) is not changed

stl::reverse (msv,first,last)
Reverses the order of the elements in sv[first,last).

stl::reverse_copy (sv,first,last) (msv,first)
same as reverse except that the reversed sequence is copied to (msv,first) and sv[first,last) is not changed.

stl::rotate (msv,first,middle,last)
rotates the elements of msv[first,middle,last] so that middle becomes the first element of msv[first,last].

stl::rotate_copy (msv,first,middle,last) (msv,first)
same as rotate except that the rotated sequence is copied to (msv,first) and sv[first,last) is not changed.

stl::random_shuffle (msv,first,last) int::seed
randomly reorders the elements in msv[first,last]

stl::partition (msv,first,last) unary_pred
places the elements in msv[first,last) that satisfy unary_pred before those that don’t. Returns middle, where msv [first,middle) contains all of the elements that satisfy unary_pred, and msv [middle, last) contains those that do not

stl::stable_partition (msv,first,last) unary_pred
same as partition except that the relative positions of the elements in each group are preserved

13.7.3 Examples
See ut_modifying.pure in the pure-stlvec/ut directory.

13.8 STL Sort Algorithms

The stlvec::sort module provides an interface to the STL’s sorting and binary search algorithms.

13.8.1 Imports
To use the operations of this module, add the following import declaration to your program:
using stlvec::sort;

All of the functions are in the stl namespace.

13.8.2 Operations
All of the functions in this module require the caller to supply an ordering function, comp. The functions (<) and (>) are commonly passed as comp.

stl::sort (msv, first, last) comp
sorts msv[first, last]
stl::stable_sort (msv, first, last) comp
  sorts msv[first, last), preserving the relative order of equal members

stl::partial_sort (msv, first, middle, last) comp
  fills msv[first, middle) with the elements of msv[first,last) that would appear there if
  msv[first,last) were sorted using comp and fills msv[middle,last] with the remaining
  elements in unspecified order

stl::partial_sort_copy (sv, first1, last1) (msv, first2, last2) comp
  let n be the number of elements in sv[first1, last1) and r be the number of elements
  in msv[first2, last2). If r < n, partial_sort_copy fills msv[first2, last2) with the first
  r elements of what sv[first1, last1) would be if it had been sorted. If r >= n, it fills
  msv[first2, first2+n) with the elements of sv[first1, last1) in sorted order. sv[first1,last1]
  is unchanged

stl::nth_element (msv, first, middle, last) comp
  rearranges the elements of msv[first, last) as follows. Let n be middle - first, and let x
  be the nth smallest element of msv[first, last). After the function is called, sv!middle
  will be x. All of the elements of msv[first, middle) will be less than x and all of the
  elements of msv[middle+1, last) will be greater than x

The next four functions assume that sv[first, last) is ordered by comp.

stl::lower_bound (sv, first, last) x comp
  returns an int designating the first position into which x can be inserted into sv[first,
  last) while maintaining the sorted ordering

stl::upper_bound (sv, first, last) x comp
  returns an int designating the last position into which x can be inserted into sv[first,
  last) while maintaining the sorted ordering

stl::equal_range (sv, first, last) x comp
  returns a pair of ints, (lower, upper) where lower and upper would have been returned
  by separate calls to lower_bound and upper_bound.

stl::binary_search (sv, first, last) x comp
  returns true if x is an element of sv[first, last)

13.8.3 Examples

See ut_sort.pure in the pure-stlvec/ut directory.

13.9 STL Merge Algorithms

The stlvec::merge module provides an interface to the STL’s merge algorithms. These algo-

rithms operate on sorted ranges.

13.9.1 Imports

To use the operations of this module, add the following import declaration to your program:
using stlvec::merge;

All of the functions are in the stl namespace.

13.9.2 Operations

All of the functions in this module require the caller to supply an ordering function, comp (as for the Pure library sort function). They only work properly on input ranges that have been previously sorted using comp. The set operations generally do not check for range overflow because it is not generally possible to determine the length of the result of a set operation until after it is completed. In most cases you will get a nasty segmentation fault if the result is bigger than the target range. The best way to avoid this possibility it to use a back iterator to specify the target range.

See parameter naming conventions at..

stl::merge(sv1,first1,last1) (sv2,first2,last2) (msv,p) comp
merges the two sorted ranges into the sorted range msv[p,p+n) where n is the total length of the merged sequence

stl::inplace_merge(msv,first,middle,last) comp
merges msv[first,middle) and msv[middle,last) into the sorted range msv[first,last]

stl::includes(sv1,first1,last1) (sv2,first2,last2) comp
returns true if every element of sv2[first2,last2) is an element of sv1[first1,last1)

stl::set_union(sv1,first1,last1) (sv2,first2,last2) (msv,p) comp
places the sorted union of sv1[first1,last1) and sv2[first2,last2) into msv[p,p+n) where n is the number of elements in the sorted union, and returns the past-the-end position of the sorted union

stl::set_intersection(sv1,first1,last1) (sv2,first2,last2) (msv,p) comp
places the sorted intersection of sv1[first1,last1) and sv2[first2,last2) into msv[p,p+n) where n is the number of elements in the sorted intersection, and returns p+n (or stl::svend, if applicable)

stl::set_difference(sv1,first1,last1) (sv2,first2,last2) (msv,p) comp
places the sorted difference of sv1[first1,last1) and sv2[first2,last2) into msv[p,p+n) where n is the number of elements in the sorted difference, and returns p+n (or stl::svend, if applicable)

stl::set_symmetric_difference(sv1,first1,last1) (sv2,first2,last2) (msv,p) comp
places the sorted symmetric_difference of sv1[first1,last1) and sv2[first2,last2) into msv[p,p+n) where n is the number of elements in the sorted symmetric_difference, and returns returns p+n (or stl::svend, if applicable)

13.9.3 Examples

See ut_merge.pure in the pure-stlvec/ut directory.

13.9.2 Operations
13.10 STL Heap Algorithms

The stlvec::heap module provides an interface to the STL’s heap operations.

13.10.1 Imports

To use the operations of this module, add the following import declaration to your program:

```cpp
using stlvec::heap;
```

All of the functions are in the stl namespace.

13.10.2 Operations

All of the functions in this module require the caller to supply an ordering function, comp (as for the Pure library sort function). The functions (<) and (>) are commonly passed as comp.

```cpp
stl::make_heap(msv, first, last) comp
```

rearranges the elements of msv[first,last) so that they are a heap, i.e., after this msv!first will be the largest element in msv[first,last), and push_heap and pop_heap will work properly

```cpp
stl::push_heap(msv, first, last) comp
```

makes msv[first,last) a heap (assuming that msv[first,last-1) was a heap)

```cpp
stl::pop_heap(msv, first, last) comp
```

swaps msv!first with msv!(last-1), and makes msv[first,last-1) a heap (assuming that msv[first,last) was a heap)

```cpp
stl::sort_heap(msv, first, last) comp
```

sorts the elements in msv[first,last)

13.10.3 Examples

See ut_heap.pure in the pure-stlvec/ut directory.

13.11 Min/Max STL Algorithms

The stlvec::minmax module provides an interface to a few additional STL algorithms.

13.11.1 Imports

To use the operations of this module, add the following import declaration to your program:

```cpp
using stlvec::minmax;
```

All of the functions are in the stl namespace.
13.11.2 Operations

All of the functions in this module require the caller to supply an ordering function, comp (as for the Pure library sort function). The functions (<) and (>) are commonly passed as comp.

stl::min_element (sv,first,last) comp
  returns the position of the minimal element of sv[first,last) under the ordering defined by comp

stl::max_element (sv,first,last) comp
  returns the position of the maximal element of sv[first,last) under the ordering defined by comp

stl::lexicographical_compare (sv1,first1,last1) (sv2,first2,last2) comp
  compares sv1[first1,last1) and sv2[first2,last2) element by element according to the ordering defined by comp, and returns true if the first sequence is less than the second

Algorithms are provided for stepping through all the permutations the elements of a stlvec. For these purposes, the first permutation has the elements of msv[first,last) sorted in ascending order and the last has the elements sorted in descending order.

stl::next_permutation (msv,first,last) comp
  rearranges msv[first,last) to produce the next permutation, in the ordering imposed by comp. If the elements of the next permutation is ordered (ascending or decending) by comp, return false. Otherwise return true.

stl::prev_permutation (msv,first,last) comp
  next_permutation in reverse

13.11.3 Examples

See ut_minmax.pure in the pure-stlvec/ut directory.

13.12 STL Numeric Algorithms

The stlvec::numeric module provides an interface to the STL’s numeric algorithms.

13.12.1 Imports

To use the operations of this module, add the following import declaration to your program:

```cpp
using stlvec::numeric;
```

All of the functions are in the stl namespace.

13.12.2 Operations

stl::accumulate (sv,first,last) x bin_fun
  accumulate bin_fun over x and the members of sv[first,last), like foldl
stl::inner_product (sv1.first1,last1) (sv2.first2,last2) x bin_fun1 bin_fun2
initialize ret with x. Traverse pairs of elements of sv1[first1,last1] and sv2[first2,last2],
denoted by (e1, e2), replacing ret with (bin_fun1 ret $ bin_fun2 e1 e2). The number
pairs traversed is equal to the size of sv1[first1,last1]

stl::partial_sum (sv.first,last) (msv, p) bin_fun
accumulate bin_fun f over the elements of sv[first1,last1], placing intermediate results
in msv[p,p+n), where n is last - first, and returns q where m is q - n and msv[m,q) is
the intermediate sequence

stl::adjacent_difference (sv,first,last) (msv, p) bin_fun
produce a sequence of new elements by applying bin_fun to adjacent elements of
sv[first,last), placing the new elements in msv[p,p+n), where n is last - first, with the
intermediate results, and returns q where m is q - n and msv[m,q) is the new sequence

13.12.3 Examples
See ut_numeric.pure in the pure-stlvec/ut directory.

13.13 Reference Counting
The following function, also in the stl namespace, is available if you want to observe how
pure-stlvec maintains reference counts for items in its containers.

stl::refc x
returns the x’s reference count (maintained by the Pure runtime for garbage collection
purposes)

13.14 Backward Compatibility
This section documents changes in pure-stlvec that might have introduced backward com-
patibility issues.

13.14.1 pure-stlvec-0.2
Bug fixes.

13.14.2 pure-stlvec-0.3
Version 0.3 reflects some changes made to make pure-stlvec consistent with its sister package,
pure-stlmap.
The update function was deprecated. Please use replace instead.
The replace function was added to the stlvec module. This function is the same as update
except that “replace sv i x” returns x instead of sv.
The `stl::replace` function was removed from the stlvec/modifying module. You can use “`stl::replace_if (sv,first,last) (x==) y`” instead of “`stl::replace (sv,first,last) x y`” to replace all instances of `x` in the specified range.

The function `null` was removed and `stl::empty` was added to replace it.

The function `list` was removed. You can use `members` instead.

The function `stl::random_shuffle` was changed to take a seed as a second parameter.

All of the tracing functions were removed.

### 13.14.3 pure-stlvec-0.4

Fixed (>) predicate operating on plain old data when passed to STL algorithms.
Chapter 14

Gnumeric/Pure: A Pure Plugin for Gnumeric

Version 0.16, October 31, 2018

Albert Gräf <aggraef@gmail.com>

Gnumeric/Pure is a Gnumeric extension which lets you use Pure functions in Gnumeric, the Gnome spreadsheet. It offers better execution speed than the existing Perl and Python plugins, and provides some powerful features not found in other Gnumeric scripting plugins, such as asynchronous data sources created from Pure streams.

Note: This module is currently unsupported. It requires (and should still work) with Gnumeric < 1.12.43, but it does not compile with Gnumeric 1.12.43 (and later) any more, since that version has major changes in its plugin API, breaking existing 3rd party plugins.

14.1 Introduction

This package provides a Gnumeric extension which gives you access to the Pure programming language in Gnumeric. It works pretty much like the Perl and Python plugin loaders which are distributed with Gnumeric, but Gnumeric/Pure offers some powerful features which aren’t found in other Gnumeric scripting plugins:

- Pure is a functional programming language which fits the computational model of spreadsheet programs very well.
- Pure is based on term rewriting and thus enables you to do symbolic computations in addition to the usual numeric calculations.
- Pure has a built-in MATLAB/Octave-like matrix data structure which makes it easy to deal with cell ranges in a spreadsheet in an efficient manner.
- Pure also provides a bridge to Octave so that you can call arbitrary Octave functions using this extension.
• Pure also has built-in support for lazy data structures and thus allows you to handle potentially infinite amounts of data such as the list of all prime numbers. Gnumeric/Pure lets you turn such lazy values into asynchronous data sources computed in the background, which update the spreadsheet automatically as results become available.

• Last but not least, Pure is compiled to native code on the fly. This means that, while startup times are a bit longer due to Pure’s JIT compiler kicking in (you’ll notice this if you open a spreadsheet with Pure functions), the resulting compiled code then typically executes much faster than equivalent interpreted Perl and Python code.

Once the plugin loader is installed and enabled, you can try the Pure functions in the provided examples and start adding your own plugin scripts. As of version 0.12, there’s a new helper script pure-gnm which generates the required plugin.xml files to make this easy. Various examples can be found in the examples folder in the distribution, which should help you to get started with Gnumeric/Pure fairly quickly.

For more advanced uses, Gnumeric/Pure also provides a programming interface which lets you do various special tasks such as modifying entire ranges of cells with one Pure call, calling Gnumeric functions from Pure, and setting up asynchronous data sources. The manual explains all this in detail.

Note: This manual assumes that you’re already familiar with Gnumeric as well as the Pure language and its programming environment. If not then you should consult the corresponding documentation to learn more about these.

14.2 Copying

Copyright (c) 2009-2017 by Albert Graef.

Gnumeric/Pure is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 2 of the License, or (at your option) any later version.

Gnumeric/Pure is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

14.3 Installation

Obviously, you need to have both Pure and Gnumeric installed. Pure 0.36 and Gnumeric 1.9.13 or later are known to work. The current release of this module will work with the latest, GTK3-based versions of Gnumeric (Gnumeric 1.11 and later, various versions starting from 1.12.23 have been tested and are known to work).
Please note that the Gnumeric plugin interface is a moving target, which means that from
time to time the gnumeric-pure module sources are updated to accommodate the latest
changes in Gnumeric. Thus, depending on which Gnumeric version you are running, you
may have to go with an older version of gnumeric-pure. In particular, if you are still running
Gnumeric 1.10 or earlier then you should use version 0.12 of the module instead:

https://bitbucket.org/purelang/pure-lang/downloads/gnumeric-pure-
0.12.tar.gz

Run make to compile the software. You might have to adjust the settings at the beginning
of the Makefile to make this work. Once the compile goes through, you should now have a
pure_loader.so file in the pure-loader subdirectory. You can install the plugin and related
stuff with sudo make install in the global Gnumeric plugin directory, or if you prefer to
install it into your personal plugin directory then run make install-local instead. (The
latter is recommended if you plan to customize any of the sample plugin scripts included in
the distribution for your purposes.)

Typically, make install and make install-local will install the plugins into the following
directories by default (here and in the following <version> denotes the version of Gnumeric
you have installed):

- System-wide installations go into /usr/local/lib/gnumeric/<version>/plugins or
  similar, depending on Gnumeric’s installation prefix (usually either /usr/local or
  /usr).
- User-specific installations go into ~/.gnumeric/<version>/plugins.

The Makefile tries to guess the installation path and version number of Gnumeric on its
own. If it guesses wrong, you can change these using the Makefile variables prefix and
gnmversion, respectively. For instance:

$ make prefix=/usr gnmversion=1.12.4

In either case, make install also installs the pure-gnm helper script under the Pure instal-
lation prefix. (This is a little convenience script to generate the plugin.xml files used by
Gnumeric to load a plugin; see Defining Your Own Functions for details.)

If make install doesn’t work for some reason, you can also just copy the pure-func and
pure-loader directories manually to your Gnumeric plugin directory. You can still run make
install in the pure-gnm subdirectory to get the pure-gnm script installed in this case.

14.4 Setup

Once Gnumeric/Pure has been properly installed, you should see it in Gnumeric’s
Tools/Plug-ins dialog. There are actually two main entries, one labelled “Pure functions”
and the other one labelled “Pure plugin loader”. You need to enable both before you can
start using Pure functions in your Gnumeric spreadsheets.

Gnumeric doesn’t provide much in the way of GUI customization options right now, but at
least it’s possible for plugins to install and configure additional menu and toolbar options.
Gnumeric/Pure adds three additional options to the Tools menu which allow you to stop
asynchronous data sources, reload Pure scripts and edit them. After installation, the definitions of these items can be found in the pure-loader/pure-ui.xml file in your Gnumeric plugin directory. Have a look at this file and edit it as desired. E.g., if you want to put the Pure-related options into a submenu and enable toolbar buttons for these options, then your pure-ui.xml file should look as follows:

```xml
<ui>
  <menubar>
    <menu name="Tools" action="MenuTools">
      <separator/>
    </menu>
    <menu name="Pure" action="PureMenu">
      <menuitem action="PureStop"/>
      <menuitem action="PureReload"/>
      <menuitem action="PureEdit"/>
    </menu>
  </menubar>
  <toolbar name="StandardToolbar">
    <separator/>
    <toolitem action="PureStop"/>
    <toolitem action="PureReload"/>
    <toolitem action="PureEdit"/>
  </toolbar>
</ui>
```

### 14.5 Basic Usage

With Pure/Gnumeric installed and enabled, you should be ready to join the fun now. Start up Gnumeric, click on a cell and invoke the “f(x)” dialog. The Pure functions available for use are shown in the “Pure” category. E.g., click on `pure_hello`. Now the Pure interpreter will be loaded and the function description displayed. Click “Ok” to select the `pure_hello` function and then “Ok” again to actually insert the function call (without arguments) into the current cell. You should now be able to read the friendly greeting returned by the function.

Of course, you can also enter the function call directly as a formula into a cell as usual. Click on a cell, then enter the following:

```
=pure_hello(getenv("USER"))
```

The greeting should now be displayed with your login name in it.

Play around a bit with the other Pure functions. These functions are nothing special; they are just ordinary Pure functions which are defined by the `pure_func.pure` script in the `pure-func` subdirectory of your Gnumeric plugin directory. You can have a look at them by invoking the “Edit Pure Scripts” option which gets added to the Tools/Pure menu once the Pure plugin loader is enabled. (This will invoke the emacs editor by default, or the editor named by the `EDITOR` environment variable. You can set this environment variable in your shell’s startup files.) The Tools/Pure menu contains a second Pure-related option, “Reload Pure Scripts” which can be used to quickly reload all loaded Pure scripts after edits; more about that later.
Please note that most of the functions in pure_func.pure are rather useless, they are only provided for illustrative purposes. However, there are some useful examples in there, too, in particular:

- **pure_eval** lets you evaluate any Pure expression, given as a string in its first argument. E.g., try something like `=pure_eval("foldl (+) 0 (1..100)")`. Additional parameters are accessible as `x!0`, `x!1`, etc. For instance: `=pure_eval("x!0+x!1", A1, B1)`.

- **pure_echo** just displays its arguments as a string in Pure syntax, as the interpreter sees them. This is useful for debugging purposes. E.g., `=pure_echo(A1:B10)` shows the given range as a Pure matrix.

- **pure_shell** is a variation of **pure_eval** which executes arbitrary Pure code and returns the last evaluated expression (if any) as a string. This is mainly provided as a convenience to create an “interactive Pure shell” which lets you evaluate Pure code inside Gnumeric. To these ends, simply prepare a text cell for entering the code to be evaluated, and then apply **pure_shell** on this text cell in another cell to display the result.

A spreadsheet showing most of the predefined functions in action can be found in pure-examples.gnumeric example distributed with Gnumeric/Pure.

### 14.6 Interactive Pure Shell

The pure-examples.gnumeric spreadsheet also includes an instance of **pure_shell** which lets you evaluate arbitrary Pure code in the same interpreter instance that executes Gnumeric/Pure functions. This is very helpful if you’re developing new Pure functions to be used in Gnumeric. It also lets you use Gnumeric as a kind of GUI frontend to the Pure interpreter. You can try this now. Open the pure-examples spreadsheet in Gnumeric and enter the following into the input cell of the Pure shell:

```
> scanl (+) 0 (1..20)
[0, 1, 3, 6, 10, 15, 21, 28, 36, 45, 55, 66, 78, 91, 105, 120, 136, 153, 171, 190, 210]
```

Note that here and in the following the prompt `>` indicates a Pure expression to be evaluated in Gnumeric (rather than the standalone Pure interpreter), which is followed by another line indicating the result (printed in the output cell below the input cell of the Pure shell). You can find the Pure shell at the bottom of the first sheet in pure-examples, see the screenshot below. For your convenience, there’s also a second, bigger one on the second sheet. You might want to copy this over to a separate spreadsheet which you can use as a scratchpad for experimentation purposes.

**Interactive Pure Shell**

<table>
<thead>
<tr>
<th>Enter any Pure expression below (See the second sheet for a bigger command line.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; scanl (+) 0 (1..20)</td>
</tr>
<tr>
<td>[0, 1, 3, 6, 10, 15, 21, 28, 36, 45, 55, 66, 78, 91, 105, 120, 136, 153, 171, 190, 210]</td>
</tr>
</tbody>
</table>

Figure 14.1: The Pure shell.
Also note that this is in fact *Pure code* (not a Gnumeric formula) being evaluated there. You can execute any Pure code, including Pure declarations, so you can type:

```
> using system; puts "Hello, world!";
  14
```

This prints the string "Hello, world!" on standard output, visible in the terminal window where you launched Gnumeric. Here is another example, showing how you can invoke any function from the C library, by declaring it as a Pure `extern` function:

```
> extern int rand(); [rand | i = 1..5];
  [1810821799, 2106746672, 1436605662, 1363610028, 695042099]
```

All functions in the Pure prelude are readily available in the Gnumeric Pure shell, as well as the functions defined in `pure_func.pure` and its imports, including the programming interface described in Advanced Features. For instance, here’s how you can retrieve a cell value from the current sheet:

```
> get_cell "A1" "Gnumeric/Pure Examples"
```

Using call (see Calling Gnumeric from Pure), you can also invoke any Gnumeric function:

```
> call "product" (1..10)
  3628800.0
```

### 14.7 Defining Your Own Functions

After playing around with `pure_func.pure` and the interactive Pure shell for a while, of course you will want to write your own functions, that’s what this extension is about after all! This section shows you how to do this.

#### 14.7.1 Creating a Simple Plugin

Let’s consider a simple example: the factorial function. In Pure this function can be implemented as follows:

```
factorial [x] = foldl (*) 1 (1..x);
```

Note the list bracket around the argument `x`. You wouldn’t normally pass a single numeric argument that way in Pure, but this is needed here since by default Gnumeric passes arguments as a list to a Pure function. There are other ways to configure the call interface to Pure functions, but these require that we tell Gnumeric about the number and types of arguments, see Gnumeric/Pure Interface below. For the moment let’s stick to the default scheme, however, in order to keep things simple.

Put the above definition into a script file, say, `myplugin.pure`. Next we need to create a `plugin.xml` file to tell Gnumeric about our plugin and which functions it provides. While these files can be written by hand, this is tedious and error-prone. Fortunately, recent Gnumeric/Pure versions provide the `pure-gnm` helper script which makes this quite easy. To use
pure-gnm with our plugin script, we have to add a special “hashbang” comment block to our
script which supplies the needed information. In our case, this might look as follows:

```plaintext
#! N: My Pure functions
#! C: Pure
#! D: My Pure functions.
#! F: factorial
```

You can add this comment block anywhere in your plugin script, but usually it is placed
near the beginning. The different fields have the following meaning:

- **N**: the name of the plugin
- **C**: the function category
- **D**: a more detailed description of the plugin
- **F**: a whitespace-delimited list of Pure function names

The contents of the **N** and **D** fields (name and description) are visible in Gnumeric’s “Plugin
Manager” dialog. You should specify at least the name field (otherwise the plugin will be
displayed as “Unnamed” in the dialog), while the description is optional (if you don’t specify
one, the description of the plugin will be empty). The **C** field denotes the category under
which the functions listed in the **F** field will be shown in Gnumeric’s “f(x)” dialog; if you
don’t specify this, the functions will be in the “Unknown” category. The **F** field is the most
crucial part. It must contain all Pure functions defined in the plugin script or its imports that
you want to be visible in Gnumeric, so you have to keep this in sync with the actual function
definitions in the script; if you don’t specify this, the plugin will provide no functions at all.

The **D** and **F** fields can also be split into multiple lines (each prefixed with the “hashbang”
comment marker and the corresponding field identifier) if necessary.

So our `myplugin.pure` script now looks like this:

```plaintext
#! N: My Pure functions
#! C: Pure
#! D: My Pure functions.
#! F: factorial

factorial [x] = foldl (*) 1 (1..x);
```

Once you’ve added the comment block, you can generate the `plugin.xml` file for the plugin
simply as follows:

```
$ pure-gnm myplugin.pure > plugin.xml
```

Note that by default `pure-gnm` writes the `plugin.xml` file to standard output which is useful
if you want to check the generated file first. To actually create the file, we simply redirect the
output to `plugin.xml`.

You’ll have to redo this every time your plugin changes (i.e., you’ve added new functions or
deleted or renamed old ones, or changed the name or description of the plugin). It’s easy to
automate this step using make. E.g., the following Makefile will do the trick:
myplugin = myplugin.pure

all: plugin.xml

plugin.xml: $(myplugin)
    pure-gnm $< > $@

clean:
    rm -f plugin.xml

Now you can just run make in the plugin directory and it will rebuild the plugin.xml file as needed.

14.7.2 The plugin.xml File

The plugin.xml file resulting from the previous step looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="Gnumeric_myplugin">
    <information>
        <name>My Pure functions</name>
        <description>My Pure functions.</description>
        <require_explicit_enabling/>
    </information>
    <loader type="Gnumeric_PureLoader:pure">
        <attribute name="module_name" value="myplugin.pure"/>
    </loader>
    <services>
        <service type="function_group" id="myplugin">
            <category>Pure</category>
            <functions>
                <function name="factorial"/>
            </functions>
        </service>
    </services>
</plugin>
```

You can also edit this file by hand if you know what you’re doing; in that case, please check the Gnumeric documentation for details about the format of these files. The template used by pure-gnm to generate these files can be found in the source distribution (see plugin.xml in the pure-gnm folder) or under /usr/local/lib/pure-gnm after installation. You can edit this file (carefully!) in order to implement global changes that you want to be in every plugin.xml file generated by pure-gnm.

Two specific items that you might want to edit by hand are the <require_explicit_enabling/> tag and the id properties of the <plugin> and <service> tags:

- The <require_explicit_enabling/> tag indicates that Gnumeric shouldn’t enable the new plugin until you explicitly tell it to. You can remove that line if you want Gnumeric to automatically enable new plugins as they are added to the system.
• The `pure-gnm` script automatically derives the id properties of the `<plugin>` and `<service>` tags from the name of the plugin script, which is a sensible default in most cases. However, you might have to change these identifiers if they happen to collide with other Gnumeric plugins and services. This can be done by either editing the generated `plugin.xml` file or by renaming the plugin script accordingly.

Note that the only really Pure-specific part in the xml file is the loader description which also names the Pure script implementing the plugin in the value of the `module_name` attribute. In this case this is just "myplugin.pure". This path is taken relative to the directory containing the `plugin.xml` file, but you can also specify an absolute path there if you want to keep the plugin script elsewhere. To achieve this with `pure-gnm`, you can just invoke it with an absolute path name, e.g.:

```
$ pure-gnm $PWD/myplugin.pure > plugin.xml
```

Now you can move the `plugin.xml` file wherewher you like and still have Gnumeric find the script file in its prescribed location. Again, this can be automatized using `make` fairly easily; we’ll return to that in the following section.

### 14.7.3 Loading the Plugin

We now have the plugin script `myplugin.pure` and the `plugin.xml` file in the same directory, say, `/some/path/myplugin`. We still need to tell Gnumeric about the new plugin, though, so that it can find it. Unfortunately, the mechanics of making a plugin known to Gnumeric are somewhat involved, so we discuss the necessary steps in detail below. There are basically three ways you can go about this:

• If you want to keep plugin script and the `plugin.xml` file where they are, you’ll have to change Gnumeric’s plugin path so that it includes the `parent` directory `/some/path` (not `/some/path/myplugin`). This is done by adding the directory under the Directories tab in Gnumeric’s Tools/Plug-ins dialog, after which you’ll have to restart Gnumeric so that it picks up the changes in the plugin search path.

• Second, you can also move or copy the entire `/some/path/myplugin` directory to your personal Gnumeric plugin folder (usually `~/.gnumeric/<version>/plugins`). Gnumeric will always search this directory for new plugins by default, so modifying the plugin search path is not necessary. However, keeping the plugin script in a hidden location in your home directory may not be very convenient if you want to modify the script later.

• Third, you can get the best of both previous methods by keeping the plugin script where it is and copying just the `plugin.xml` file to your personal Gnumeric plugin folder.

The third method tends to be the easiest, but note that it requires that the plugin script needs to be specified as an absolute path (as sketched out previously). Fortunately, it’s fairly easy to automate this with `make`. The following requires GNU make to work, and you’ll also need to have the Gnumeric development files installed, so that the Gnumeric version can be determined easily with a shell command. These rules are to be added to the end of the Makefile described previously under Creating a Simple Plugin.
Now you can just run `make install` to make the plugin known to Gnumeric. Note that we also added a rule that allows you to uninstall the plugin if it isn’t needed any more.

In any case, once you fire up Gnumeric again, the new plugin should be listed as “My Pure functions” on the Plugin List tab in the Tools/Plug-ins dialog. Check it to enable it. The `factorial` function defined in the plugin should now be available and ready to be called just like any other Gnumeric function. For instance, type this into a cell to have the factorial of 10 computed:

```
=factorial(10)
```

Also try saving the spreadsheet and loading it again after restarting Gnumeric. The plugin will now be loaded automatically and the spreadsheet should display the proper value of the factorial.

**Note:** Once you start playing around with your own Pure plugins, you may run into one common mishap: You open an existing spreadsheet without having enabled the plugins it uses. An easily visible symptom of that is that you’ll see cells showing the "#NAME?" error. You will then have to enable those plugins again and reload the spreadsheet afterwards, so that everything is recalculated properly.

In contrast, just changing the body of a function in a plugin usually needs neither a restart of Gnumeric nor a reloading of the spreadsheet. In this case it’s often sufficient to reload all scripts with the “Reload Pure Scripts” option in the Tools/Pure menu, after which you can use “Recalculate” (F9) to recompute the spreadsheet.

It is also worth mentioning here that the Pure loader can load multiple Pure plugins (and of course each plugin can provide as many functions as you want). You only need to tell Gnumeric about them after creating the scripts and `plugin.xml` files and placing them into corresponding plugin directories. Just enable the ones that you want in Tools/Plug-ins. All scripts are loaded in the same Pure interpreter (and thus are treated like one big script) so that functions in one script can use the function and variable definitions in another. If you need to access the definitions in the `pure_func.pure` “mother script”, you can also just import it into your scripts with a using clause, i.e.:

```
using pure_func;
```

Another important point is that a Pure plugin script is always loaded in the directory where it is located, as indicated by the corresponding `plugin.xml` file, even if it is different from the plugin directory. That is, the current working directory (which is normally the directory that Gnumeric was started in) is temporarily set to the directory holding the plugin
script while the script is being loaded. This enables the script to find imported scripts and other files (such as media files or scripts written in other languages) that it may need at load time. This wasn’t needed in this simple example, but you can find other examples in the Gnumeric/Pure distribution which make good use of this feature.

### 14.7.4 Spicing It Up

Our plugin example is now essentially complete, but in order to make it really convenient to use, we may want to add some information about how the `factorial` function is to be called in Gnumeric. Gnumeric doesn’t keep this kind of information in the `plugin.xml` file, but expects it to be provided by the plugin itself. In the Gnumeric/Pure interface this can be done by adding a rule for the `gnm_info` function. In our example we tell Gnumeric that `factorial` expects a single numeric argument. While we’re at it, we might as well add some helpful documentation to be displayed in Gnumeric’s “f(x)” dialog. The details of this are described in the following section, but to give you a sneak preview, here’s a beefed-up version of our script which implements all this (you can also find this version of the example along with a GNU Makefile in the Gnumeric/Pure distribution):

```plaintext
#!/ N: My Pure functions
#!/ C: Pure
#!/ D: My Pure functions.
#!/ F: factorial

factorial x = foldl (*) 1 (1..x);

using pure_func; // for the gnm_help function

fn_info "factorial" = "f", fn_help "factorial:factorial of a number"
  ["x:integer"] "Computes the factorial of @{x}."
  [] ["=factorial(10)"] [];
```

Fire up Gnumeric again, press the “f(x)” button and select `factorial` under the Pure category. The “f(x)” dialog should now display the additional information we added above. Also note that Gnumeric now knows that this function is supposed to be called with exactly one f (numeric) argument. Therefore the list brackets around the argument of `factorial` aren’t needed any more, so don’t forget to remove them, as shown in the above code sample.

This completes our little example. As an exercise, you’re invited to add more functions on your own. (Don’t forget to change the `#! F` line accordingly and rerun `pure-gnm` when you do this, so that Gnumeric knows about the new functions.) It also pays off to take a look at some of the other included examples, you can find these in the examples folder of the distribution tarball.

### 14.8 Gnumeric/Pure Interface

We already explained in the previous section that, when a Pure function is called from Gnumeric, it receives its arguments in a list by default. However, it is possible to tell Gnumeric about the expected arguments of the function and also specify a help text to be displayed in the “f(x)” dialog, by giving a definition of the `gnm_info` function as explained below.
Note that gnm_info is really an ordinary Pure function. Thus, rather than hardcoding this information as static text (such as the “docstrings” used in Gnumeric’s Python extension), the function descriptions can also be constructed dynamically in corresponding Pure code. This offers an opportunity for programmatic customizations. But note that the gnm_info function will only be invoked when the plugin script is loaded, so once that is done the function description remains the same for the entire Gnumeric session.

14.8.1 Function Descriptions

To describe a given function to Gnumeric, define gnm_info "<name>" (where <name> is the name of the function) as a pair with the following elements:

- The first element, a string, gives the signature of the function. E.g., "" denotes a function without arguments, "f" a function taking a single float parameter, "fs" a function taking a float and a string argument (in that order), etc. Optional parameters can be indicated using |, as in "ff|s" (two non-optional floats, followed by an optional string). See below for a complete list of the supported parameter types.

- The second element is a list of hash pairs key=>text which together make up the help text shown in Gnumeric’s “f(x)” dialog. You should at least specify the function name along with a short synopsis here, e.g. GNM_FUNC_HELP_NAME => "frob: the frob function". Parameter descriptions take the form GNM_FUNC_HELP_ARG => "x:integer". There are a number of other useful elements, see below for details.

Both the signature and the function description are optional. That is, gnm_info may return either just a signature string, or a list of hash pairs with the function description, or both. The signature defaults to a variadic function which takes any number of parameters of any type (see below), and the description defaults to some boilerplate text which says that the function hasn’t been documented yet.

Note that if no signature is given, then the function accepts any number of parameters of any type. In that case, or if there are optional parameters, the function becomes variadic and the (optional) parameters are passed as a Pure list (in addition to the non-optional parameters).

Here’s the list of valid parameter types, as they are documented in the Gnumeric sources:

- f : float no errors, string conversion attempted
- b : boolean identical to f
- s : string no errors
- S : scalar any non-error scalar
- E : scalar any scalar, including errors
- r : cell range content may not be evaluated yet
- A : area array, range (as above), or scalar
- ? : anything any value (scalars, non-scalars, errors, whatever)

The keys used in the function description may be any of the following, along with sample text for each type of field:

- GNM_FUNC_HELP_NAME => "name:synopsis"
- GNM_FUNC_HELP_ARG => "name:parameter description"
The following keys are only supported in the latest Gnumeric versions:

- **GNM_FUNC_HELP_EXTREF** => "wiki:en:Trigonometric_functions"
- **GNM_FUNC_HELP_EXCEL** => "Excel compatibility information."
- **GNM_FUNC_HELP_ODF** => "OpenOffice compatibility information."

Note that inside the descriptions, the notation @\{arg\} (@arg in older Gnumeric versions) can be used to refer to a parameter value. For instance, here’s a sample description for a binary function which also includes a help text:

```plaintext
hnman "pure_max" = "ff",
[GNM_FUNC_HELP_NAME] => "pure_max:maximum of two numbers",
[GNM_FUNC_HELP_ARG] => "x:number",
[GNM_FUNC_HELP_ARG] => "y:number",
[GNM_FUNC_HELP_DESCRIPTION] => "Computes the maximum of two numbers @{x} and @{y}.",
[GNM_FUNC_HELP_EXAMPLES] => "=pure_max(17,22)"
```

As you can see, the function descriptions are a bit unwieldy, so it’s convenient to construct them using this little helper function defined in pure_func.pure:

```plaintext
gnm_help name::string args descr::string notes examples see_also =
[GNM_FUNC_HELP_NAME] => name] +
[GNM_FUNC_HELP_ARG] => x | x::string = args ] +
[GNM_FUNC_HELP_DESCRIPTION] => descr ] +
[GNM_FUNC_HELP_NOTE] => x | x::string = notes ] +
[GNM_FUNC_HELP_EXAMPLES] => x | x::string = examples ] +
(if null see_also then [] else
[GNM_FUNC_HELP_SEEALSO] => join "," see_also]);
```

Now the description can be written simply as follows:

```plaintext
hnman "pure_max" = "ff", gnm_help "pure_max:maximum of two numbers"
["x:number", "y:number"]
"Computes the maximum of two numbers @{x} and @{y}.
["=pure_max(17,22)"
```

Since this function only has fixed arguments, it will be called in curried form, i.e., as `pure_max x y`. For instance, the actual definition of `pure_max` may look as follows:

```plaintext
pure_max x y = max x y;
```

Conversely, if no signature is given, then the function accepts any number of parameters of any type, which are passed as a list. For instance:

```plaintext
hnman "pure_sum" = gnm_help "pure_sum:sum of a collection of numbers"
[] "Computes the sum of a collection of numbers."
[] ["=pure_sum(1,2,3,4,5,6)"] ["pure_sums"];
```
Here the function will be called as \texttt{pure\_sum [x1,x2,...]}, where \texttt{x1}, \texttt{x2}, etc. are the arguments the function is invoked with. Note that in this case there may be any number of arguments (including zero) of any type, so your function definition must be prepared to handle this. If a function does not have a \texttt{gnm\_info} description at all then it is treated in the same fashion. The \texttt{pure\_func.pure} script contains some examples showing how to write functions which can deal with any numbers of scalars, arrays or ranges, see the \texttt{pure\_sum} and \texttt{pure\_sums} examples. These employ the following \texttt{ranges} function to “flatten” a parameter list to a list holding all denoted values:

\begin{verbatim}
ranges xs = cat [ case x of _::matrix = list x; _ = [x] end | x = xs ];
\end{verbatim}

E.g., the \texttt{pure\_sum} function can now be defined as follows:

\begin{verbatim}
pure\_sum xs = foldl (+) 0 (ranges xs);
\end{verbatim}

A function may also have both fixed and optional arguments (note that in what follows we’re going to omit the detailed function descriptions for brevity):

\begin{verbatim}
gnm\_info "foo" = "ff|ff";
\end{verbatim}

In this case the fixed arguments are passed in curried form as usual, while the optional parameters are passed as a list. That is, \texttt{foo} may be called as \texttt{foo x y [z]}, \texttt{foo x y [z,t]} or \texttt{foo x y [z,t]}, depending on whether it is invoked with two, three or four arguments.

### 14.8.2 Conversions Between Pure and Gnumeric Values

The marshalling of types between Gnumeric and Pure is pretty straightforward; basically, Pure numbers, strings and matrices map to Gnumeric numbers, strings and arrays, respectively. The following table summarizes the available conversions:

<table>
<thead>
<tr>
<th>Pure</th>
<th>Gnumeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{gnm_error &quot;#N/A&quot;}</td>
<td>error</td>
</tr>
<tr>
<td>4711, 4711L, 4711.0</td>
<td>scalar (number)</td>
</tr>
<tr>
<td>&quot;Hello world&quot;</td>
<td>string</td>
</tr>
<tr>
<td>()</td>
<td>empty</td>
</tr>
<tr>
<td>(1,2,3)</td>
<td>array</td>
</tr>
<tr>
<td>[1,2,3]</td>
<td>array</td>
</tr>
<tr>
<td>{1,2,3;4,5,6}</td>
<td>array (or cell range)</td>
</tr>
<tr>
<td>&quot;A1:B10&quot;</td>
<td>cell range (&quot;r&quot; conversion)</td>
</tr>
</tbody>
</table>

These conversions mostly work both ways. Note that on input, cell ranges are usually passed as matrices to Pure functions (i.e., they are passed “by value”), unless the function signature specifies a “\texttt{r}” conversion in which case the cell ranges themselves are passed to the function in string form. (Such values can also be passed on to Gnumeric functions which expect a cell range ("r") parameter, see Calling Gnumeric from Pure below.)

Conversely, matrices, lists and tuples all become Gnumeric arrays on output, so usually you’ll want to enter these as array functions (\texttt{Ctrl-Shift-Enter} in Gnumeric). As a special case, the empty tuple can be used to denote empty cell values (but note that empty Gnumeric values may become zeros when passed as float or array arguments to Pure functions).
Another special case is a term of the form `gnm_error msg`, where `msg` is a string value indicating a Gnumeric error value such as "#N/A", "#NAME?", "#NULL!", etc. When returned by a plugin function, the error text will be displayed in the corresponding Gnumeric cell.

If a Pure function returns a value that doesn’t match any of the above then it is converted to a string in Pure expression syntax and that string is returned as the result of the function invocation in Gnumeric. This makes it possible to return any kind of symbolic Pure value, but note that if such a value is then fed into another Pure function, that function will have to convert the string value back to the internal representation if needed; this can be done very conveniently using Pure’s `eval` function, see the Pure documentation for details.

14.9 Advanced Features

This section explains various additional features provided by the Gnumeric/Pure interface that should be useful for writing your own functions. Note that for your convenience all functions discussed in this section are declared in `pure_func.pure`.

14.9.1 Calling Gnumeric from Pure

It is possible to call Gnumeric functions from Pure using the `call` function which takes the name of the function (a string) as its first, and the parameters as the second (list) argument. For instance:

```pure
gnm_info "gnm_bitand" = "ff";
gnm_bitand x y = call "bitand" [x,y];
```

Note that `call` is an external C function provided by Gnumeric/Pure. If you want to use it, it must be declared in your Pure script as follows:

```pure
extern expr* pure_gnmcall(char* name, expr* args) = call;
```

However, `pure_func.pure` already contains the above declaration, so you don’t have to do this yourself if you import `pure_func.pure` in your scripts.

Also note that `call` doesn’t do any of Gnumeric’s automatic conversions on the parameters, so you have to pass the proper types of arguments as required by the function.

14.9.2 Accessing Spreadsheet Cells

Gnumeric/Pure provides the following functions to retrieve and modify the contents of spreadsheet cells and ranges of such cells:

```pure
extern expr* pure_get_cell(char* s) = get_cell;
extern expr* pure_get_cell_text(char* s) = get_cell_text;
extern expr* pure_get_cell_format(char* s) = get_cell_format;
extern expr* pure_set_cell(char* s, expr *x) = set_cell;
extern expr* pure_set_cell_text(char* s, expr *x) = set_cell_text;
extern expr* pure_set_cell_format(char* s, expr *x) = set_cell_format;
extern expr* pure_get_range(char* s) = get_range;
extern expr* pure_get_range_text(char* s) = get_range_text;
```
extern expr* pure_get_range_format(char* s) = get_range_format;
extern expr* pure_set_range(char* s, expr *x) = set_range;
extern expr* pure_set_range_text(char* s, expr *x) = set_range_text;
extern expr* pure_set_range_format(char* s, expr *x) = set_range_format;

For instance, here's how you use these functions to write and then read some cell values (try this in the interactive Pure shell):

```pure
> set_cell "A14" 42 ()
> get_cell "A14"
42.0
> set_range "A14:G14" \$ scanl (*) 1 (1..6) ()
> get_range "A14:G14" {1.0,1.0,2.0,6.0,24.0,120.0,720.0}
> set_cell_text "A14" "=sum(B14:G14)"
()>
> get_cell "A14"
873.0
> get_cell_text "A14"
"=sum(B14:G14)"
> get_range_text "A14:G14" {
"=sum(B14:G14)"","1","2","6","24","120","720"
}
```

Note that while the set_cell function sets the given cell to a constant value, set_cell_text also allows you to store a formula in a cell which will then be evaluated as usual. Similarly, get_cell retrieves the cell value, while get_cell_text yields the text in the cell, as entered by the user (which will either be a formula or the textual representation of a constant value). The set_range, set_range_text, get_range and get_range_text functions work analogously, but are used to manipulate entire ranges of cells, which can be set from Pure tuples, lists or matrices, and retrieved as Pure matrices.

Functions to retrieve and change the cell format are also provided (watch the contents of the cell A14 change its color to blue on entering the first expression):

```pure
> set_cell_format "A14" "[Blue]0.00" ()
> get_range_format "A14:C14" {
"[Blue]0.00","General","General"
}
```

There are also functions to get the position of the “current” cell (i.e., the cell from which a Pure function was called), and to translate between cell ranges in Gnumeric syntax and the corresponding internal representation consisting of a pointer to a Gnumeric sheet and the cell or range coordinates:

```pure
extern expr* pure_this_cell() = this_cell;
extern expr* pure_parse_range(char* s) = parse_range;
extern expr* pure_make_range(expr* x) = make_range;
```

Examples:
14.9.3 Asynchronous Data Sources

Gnumeric/Pure makes it easy to set up asynchronous data sources which draw values from a Pure computation executed in a background process. This facility is useful to carry out lengthy computations in the background while you can continue to work with your spreadsheet. It also allows you to process incoming data and asynchronous events from special devices (MIDI, sensors, stock tickers, etc.) in (soft) realtime.

To do this, you simply pass an expression to the datasource function. This is another external C function provided by Gnumeric/Pure, which is declared in pure_func.pure as follows:

```c
extern expr* pure_datasource(expr* x) = datasource;
```

The argument to datasource is typically a thunk or stream (lazy list) which is to be evaluated in the background. The call to datasource initially returns a #N/A value (gnm_error "#N/A") while the computation is still in progress. The cell containing the data source then gets updated automatically as soon as the value becomes available, at which point the datasource call now returns the computed value. E.g., here’s how you would wrap up a lengthy calculation as a thunk and submit it to datasource which carries out the computation as a background task:

```pure
gnm_info "pure_frob" = "f";
pure_frob x = datasource (lengthy_calculation x&);
lengthy_calculation x = sleep 3 $$ foldl (*) 1 (1..x);
```

Note that a cell value may draw values from as many independent data sources as you want, so the definition of a cell may also involve multiple invocations of datasource:

```pure
gnm_info "pure_frob2" = "ff";
pure_frob2 x y = datasource (lengthy_calculation x&),
    datasource (lengthy_calculation y&);
```

Special treatment is given to (lazy) lists, in this case datasource returns a new value each time a list element becomes available. For instance, the following function uses an infinite stream to count off the seconds starting from a given initial value:

```pure
gnm_info "pure_counter" = "f";
pure_counter x = datasource [sleep (i>x) $$ i | i = x..inf];
```

You can also try this interactively in the Pure shell:
> datasource [sleep (i>0) $$ i | i = 0..inf]
  0
  1
  ...

Here’s another example for the Pure shell which prints the prime numbers:

> datasource primes with primes = sieve (2..inf);
  sieve (p:qs) = p : (sleep 1 $$ sieve [q | q = qs; q mod p])& end
  2
  3
  5
  ...

Note that when processing a lazy list, the cell containing the call will keep changing as long as new values are produced (i.e., forever in this example). The “Stop Data Sources” option in the Tools/Pure menu can be used to stop all active data sources. “Reload Pure Scripts” also does this. You can then restart the data sources at any time by using “Recalculate” (F9) to recompute the spreadsheet.

Also note that because of the special way that datasource handles list values, you cannot return a list directly as the result of datasource, if it is to be treated as a single result. Instead, you’ll have to wrap the result in a singleton list (e.g., datasource [[[lengthy_calculation x, lengthy_calculation y]6]), or return another aggregate (i.e., a matrix or a tuple).

Finally, note that when the arguments of a call involving datasource change (because they depend on other cells which may have been updated), the computation is automatically restarted with the new parameters. The default behaviour in this case is that the entire computation will be redone from scratch, but it’s also possible to wrap up calls to datasource in a manner which enables more elaborate communication between Gnumeric and background tasks initiated with datasource. This is beyond the scope of this manual, however, so we leave this as an exercise to the interested reader.

### 14.9.4 Triggers

In addition to asynchronous data sources, the trigger function is provided to compute values or take actions depending on some external condition, such as the availability of data on a special device or the creation of some widget (see the next section):

```
extern expr* pure_trigger(int timeout, expr* cond, expr* val, expr* data)
  = trigger;
```

Thus a typical invocation of the function looks as follows:

```
trigger timeout condition value data
```

The condition and value arguments are callback functions which get invoked by trigger, passing them the given data argument. The trigger reevaluates the given condition in regular intervals (1 second in the current implementation) and, as soon as it becomes true, computes the given value and returns that value as the result of the trigger call. As long as the condition doesn’t hold, trigger returns a #N/A value (gnm_error "#N/A"). Note that,
in difference to datasource, both the condition and the value are computed in Gnumeric (rather than a child process), so that it is possible to access the current information in the loaded spreadsheet.

The timeout value determines how often the condition is checked. If it is positive, the condition will be reevaluated \( \text{timeout}+1 \) times (once initially, and then once per second for a total duration of \( \text{timeout} \) seconds). If it is negative, the trigger never times out and the condition will be checked repeatedly until the trigger expression is removed (or Gnumeric is exited). In either case value data will be recomputed each time condition data yields true. (This is most useful if the computed value, as a side effect, arranges for the condition to become false again afterwards.) Finally, if \( \text{timeout} \) is zero then the trigger fires at most once, as soon as the condition becomes true, at which point value data is computed just once.

Here’s a (rather useless) example of a trigger which fires exactly once, as soon as a certain cell goes to a certain value, and then modifies another cell value accordingly:

```plaintext
> trigger 0 (\_\_.get_cell "A14"==="Hello") (\_\_.set_cell "A15" "World") ()
```

Now, as soon as you type Hello in the cell A14, the trigger will print World in cell A15. Note that the data argument isn’t used here. A more useful example will be discussed in the following section.

### 14.9.5 Sheet Objects

Gnumeric offers some kinds of special objects which can be placed on a sheet. This comprises the chart and image objects which can be found in the “Insert” menu, as well as a number of useful graphical elements and GUI widgets on the “Object” toolbar, accessible via “View/Toolbars”. The latter are also useful for providing control input to Pure functions.

Gnumeric/Pure provides the following function to retrieve information about the special objects in a spreadsheet:

```plaintext
extern expr* pure_sheet_objects() = sheet_objects;
```

For instance, with one button object in your spreadsheet, the output of `sheet_objects` might look like this:

```plaintext
> sheet_objects
   [(["Sheet1","button","Push Me!","A11",[#<pointer 0x2a1dcd0>]])]
```

Each object is described by a tuple which lists the name of the sheet on which the object is located, the type of object, the object’s content or label (if applicable), the cell which the object is linked to (if applicable), and a list of pointers to the corresponding `GtkWidgets` (if any). Note that in general a GUI object may be associated with several widgets, as Gnumeric allows you to have multiple views on the same spreadsheet, so there will be one widget for each view an object is visible in. Also note that the content/label information depends on the particular type of object:

- List and combo widgets return the content link (referring to the cells in the spreadsheet holding the items shown in the list).
• Frame and button widgets return the label shown on the widget.
• Graphic objects like rectangles and ellipses return the text content of the object.
• Image objects (type "image/xyz", where xyz is the type of image, such as svg or png) return a pointer to the image data in this field.

The `sheet_objects` function is a bit tricky to use, since some of the objects or their associated widgets might not have been created yet when the spreadsheet is loaded. Therefore it is necessary to use a trigger to make sure that the information is updated once all objects are fully displayed. The `pure_func.pure` script contains the following little wrapper around `sheet_objects` which does this:

```plaintext
pure_objects = trigger 0 (\_.->all realized sheet_objects) 
   (\_.->matrix$map list sheet_objects) ()
with realized (_,_,_,_,w) = ~listp w || ~null w && ~any null w end;
```

See the `widgets.gnumeric` spreadsheet in the distribution for an example.

Possible uses of this facility are left to your imagination. Using Gnumeric’s internal APIs and Pure’s Gtk interface, you might manipulate the GUI widgets in various ways (add icons to buttons or custom child widgets to frames, etc.).
Chapter 15

Pure-GLPK - GLPK interface for the Pure programming language

Version 0.5, April 11, 2018

Jiri Spitz <jiri.spitz@bluetone.cz>

This module provides a feature complete GLPK interface for the Pure programming language, which lets you use all capabilities of the GNU Linear Programming Kit (GLPK) directly from Pure.

GLPK (see http://www.gnu.org/software/glpk) contains an efficient simplex LP solver, a simplex LP solver in exact arithmetics, an interior-point solver, a branch-and-cut solver for mixed integer programming and some specialized algorithms for net/grid problems. Using this interface you can build, modify and solve the problem, retrieve the solution, load and save the problem and solution data in standard formats and use any of advanced GLPK features.

The interface uses native Pure data types - lists and tuples - so that you need not perform any data conversions to/from GLPK internal data structures.

To make this module work, you must have a GLPK installation on your system, the version 4.42 or higher is required.

15.1 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure- glpk-0.5.tar.gz.

Run make to compile the module and make install (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure installed.

The default make options suppose that GLPK was configured with the following options:
--enable-dl --enable-odbc --enable-mysql --with-zlib --with-gmp
The zlib library is a part of the GLPK source distribution from the version 4.46 onwards, so the configure options for newer GLPK versions are:

```
--enable-dl --enable-odbc
--enable-mysql --with-gmp
```

Using the given options the dependencies are:

- GNU Multiprecision Library (GMP) - serves for the exact simplex solver. When disabled, the exact solver still works but it is much slower.
- ODBC library - serves for reading data directly from database tables within the GNU MathProg language translator through the ODBC interface.
- MySQL client library - serves for reading data directly from MySQL tables within the GNU MathProg language translator.
- zlib compression library - enables reading and writing gzip compressed problem and solution files.
- ltdl dlopen library - must be enabled together with any of ODBC or MySQL (or zlib for GLPK versions 4.45 and earlier).

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, `make install prefix=/usr` sets the installation prefix, and `make PIC=-fPIC` or some similar flag might be needed for compilation on 64 bit systems. The variable `ODBCLIB` specifies the ODBC library to be linked with. The default value is `ODBCLIB=-lodbc`. Please see the Makefile for details.

### 15.2 Error Handling

When an error condition occurs, the GLPK library itself prints an error message and terminates the application. This behaviour is not pleasant when working within an interpreter. Therefore, the Pure - GLPK bindings catches at least the most common errors like indices out of bounds. On such an error an appropriate message is returned to the interpreter. The less common errors are still trapped by the GLPK library.

When one of the most common errors occurs, an error term of the form `glp::error message` will be returned, which specifies what kind of error happened. For instance, an index out of bounds will cause a report like the following:

```
[Pure GLPK error] row index out of bounds
```

You can check for such return values and take some appropriate action. By redefining `glp::error` accordingly, you can also have it generate exceptions or print an error message. For instance:

```
flash::error message = fprintf stderr "%s\n" message $$ ()
```

**NOTE:** When redefining `glp::error` in this manner, you should be aware that the return value of `glp::error` is what will be returned by the other operations of this module in case of an error condition. These return values are checked by other functions. Thus the return value should still indicate that an error has happened, and not be something that might be interpreted as a legal return value, such as an integer or a nonempty tuple. It is usually safe
to have `glp::error` return an empty tuple or throw an exception, but other types of return values should be avoided.

**IMPORTANT:** It is really good to define a `glp::error` function, otherwise the errors might remain unnoticed.

### 15.3 Further Information and Examples

For further details about the operations provided by this module please see the GLPK Reference Manual. Sample scripts illustrating the usage of the module can be found in the examples directory.

### 15.4 Interface description

Most GLPK functions and symbols live in the namespace `glp`. There are a few functions and symbols in the namespace `lpx`. These functions and symbols are likely to be removed and replaced by new ones in the future.

In general, when you replace the `glp_` prefix from the GLPK Reference Manual with the namespace specification `glp::` then you receive the function name in this module. The same is valid for `lpx_` and `lpx::`. The symbolic constants are converted into lower case in this module, again obeying the same prefix rules.

### 15.5 Descriptions of interface functions

#### 15.5.1 Basic API routines

**Problem creating and modifying routines**

**Create the GLPK problem object**

**Synopsis:**

```cpp
glp::create_prob
```

**Parameters:**

```cpp
none
```

**Returns:**

```cpp
pointer to the LP problem object
```

**Example:**

```cpp
> let lp = glp::create_prob;
> lp;
</pointer 0x9de7168>
```

**Set the problem name**

**Synopsis:**

```cpp
glp::set_prob_name
```
glp::set_prob_name lp name

Parameters:

lp  pointer to the LP problem object
name  problem name

Returns:

()

Example:

> glp::set_prob_name lp "Testing problem";
()

Set objective name  Synopsis:

glp::set_obj_name lp name

Parameters:

lp  pointer to the LP problem object
name  objective name

Returns:

()

Example:

> glp::set_obj_name lp "Total costs";
()

Set the objective direction  Synopsis:

glp::set_obj_dir lp direction

Parameters:

lp  pointer to the LP problem object
direction  one of the following:
  glp::min  minimize
  glp::max  maximize

Returns:

()

Example:
Add new rows to the problem  Synopsis:

\[\text{glp::add_rows \ lp \ count}\]

Parameters:

- \text{lp}  \quad \text{pointer to the LP problem object}
- \text{count}  \quad \text{number of rows to add}

Returns:

- index of the first row added

Example:

\[
\begin{aligned}
> \ & \text{let} \ \text{first_added_row} = \text{glp_add_rows \ lp \ 3}; \\
> \ & \text{first_added_row}; \\
> \ & 6
\end{aligned}
\]

Add new columns to the problem  Synopsis:

\[\text{glp::add_cols \ lp \ count}\]

Parameters:

- \text{lp}  \quad \text{pointer to the LP problem object}
- \text{count}  \quad \text{number of columns to add}

Returns:

- index of the first column added

Example:

\[
\begin{aligned}
> \ & \text{let} \ \text{first_added_col} = \text{glp_add_cols \ lp \ 3}; \\
> \ & \text{first_added_col}; \\
> \ & 5
\end{aligned}
\]

Set the row name  Synopsis:

\[\text{glp::set_row_name \ lp \ (rowindex, rowname)}\]

Parameters:

- \text{lp}  \quad \text{pointer to the LP problem object}
- \text{rowindex}  \quad \text{row index}
- \text{rowname}  \quad \text{row name}
Returns:

()

Example:

> glp::set_row_name lp (3, "The third row");

()

Set the column name  Synopsis:

\texttt{glp::set\_col\_name \texttt{lp}} (\texttt{colindex}, \texttt{colname})

Parameters:

\begin{itemize}
  \item \texttt{lp} pointer to the LP problem object
  \item \texttt{colindex} column index
  \item \texttt{colname} column name
\end{itemize}

Returns:

()

Example:

> glp::set_col_name lp (3, "The third column");

()

Set (change) row bounds  Synopsis:

\texttt{glp::set\_row\_bnds \texttt{lp}} (\texttt{rowindex}, \texttt{rowtype}, \texttt{lowerbound}, \texttt{upperbound})

Parameters:

\begin{itemize}
  \item \texttt{lp} pointer to the LP problem object
  \item \texttt{rowindex} row index
  \item \texttt{rowtype} one of the following:
    \begin{itemize}
      \item \texttt{glp::fr} free variable (both bounds are ignored)
      \item \texttt{glp::lo} variable with lower bound (upper bound is ignored)
      \item \texttt{glp::up} variable with upper bound (lower bound is ignored)
      \item \texttt{glp::db} double bounded variable
      \item \texttt{glp::fx} fixed variable (lower bound applies, upper bound is ignored)
    \end{itemize}
  \item \texttt{lowerbound} lower row bound
\end{itemize}
**Set (change) column bounds**  
**Synopsis:**

```cpp
glp::set_col_bnds lp (colindex, coltype, lowerbound, upperbound)
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colindex` column index
- `coltype` one of the following:
  - `glp::fr` free variable (both bounds are ignored)
  - `glp::lo` variable with lower bound (upper bound is ignored)
  - `glp::up` variable with upper bound (lower bound is ignored)
  - `glp::db` double bounded variable
  - `glp::fx` fixed variable (lower bound applies, upper bound is ignored)
- `lowerbound` lower column bound
- `upperbound` upper column bound

**Returns:**

- `()`

**Example:**

```cpp
> glp::set_col_bnds lp (3, glp::db, 100.0, 150.0);
()```

**Set (change) objective coefficient or constant term**  
**Synopsis:**

```cpp
glp::set_obj_coef lp (colindex, coefficient)
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colindex` column index, zero index denotes the constant term (objective shift)

**Returns:**

- `()`

**Example:**

```cpp
> glp::set_obj_coef lp (0, coefficient);
()```

**upperbound** upper row bound

**Returns:**

- `()`

**Example:**

```cpp
> glp::set_row_bnds lp (3, glp::up, 0.0, 150.0);
()```
Load or replace matrix row  Synopsis:

```cpp
glp::set_mat_row lp (rowindex, rowvector)
```

Parameters:
- **lp** pointer to the LP problem object
- **rowindex** row index
- **rowvector** list of tuples (colindex, coefficient); only non-zero coefficients have to be specified, the order of column indices is not important, duplicates are not allowed

Returns:

```cpp
()
```

Example:

```cpp
> glp::set_mat_row lp (3, [(1, 3.0), (4, 5.2)]);
()
```

Load or replace matrix column  Synopsis:

```cpp
glp::set_mat_col lp (colindex, colvector)
```

Parameters:
- **lp** pointer to the LP problem object
- **colindex** column index
- **colvector** list of tuples (rowindex, coefficient); only non-zero coefficients have to be specified, the order of row indices is not important, duplicates are not allowed

Returns:

```cpp
()
```

Example:

```cpp
> glp::set_mat_col lp (2, [(4, 2.0), (2, 1.5)]);
()
```
Load or replace the whole problem matrix  Synopsis:

\texttt{glp::load_matrix lp matrix}

Parameters:

\texttt{lp}  pointer to the LP problem object

\texttt{matrix}  list of tuples (rowindex, colindex, coefficient); only non-zero coefficients have to be specified, the order of indices is not important, duplicates are \textbf{not} allowed

Returns:

()  

Example:

\texttt{> glp::load_matrix lp [(1, 3, 5.0), (2, 2, 3.5), (3, 1, -2.0), (3, 2, 1.0)]; ()}

Check for duplicate elements in sparse matrix  Synopsis:

\texttt{glp::check_dup numrows numcols indices}

Parameters:

\texttt{numrows}  number of rows

\texttt{numcols}  number of columns

\texttt{indices}  list of tuples (rowindex, colindex); indices of only non-zero coefficients have to be specified, the order of indices is not important

Returns:

returns one of the following:

0  the matrix has no duplicate elements

-k  rowindex or colindex of the k-th element in indices is out of range

+k  the k-th element in indices is duplicate

Remark:

Notice, that k counts from 1, whereas list members are counted from 0.

Example:

\texttt{> glp::check_dup 3 3 [(1, 3), (2, 2), (3, 1), (2, 2)]; 4}
Sort elements of the constraint matrix  

Synopsis:

```cpp
glp::sort_matrix lp
```

Parameters:

- `lp` pointer to the LP problem object

Returns:

- `()`

Example:

```
> glp::sort_matrix lp;
()`
```

Delete rows from the matrix  

Synopsis:

```cpp
glp::del_rows lp rows
```

Parameters:

- `lp` pointer to the LP problem object
- `rows` list of indices of rows to be deleted; the order of indices is not important, duplicates are not allowed

Returns:

- `()`

Remark:

Deleting rows involves changing ordinal numbers of other rows remaining in the problem object. New ordinal numbers of the remaining rows are assigned under the assumption that the original order of rows is not changed.

Example:

```
> glp::del_rows lp [3, 4, 7];
()`
```

Delete columns from the matrix  

Synopsis:

```cpp
glp::del_cols lp cols
```

Parameters:

- `lp` pointer to the LP problem object
- `cols` list of indices of columns to be deleted; the order of indices is not important, duplicates are not allowed

Returns:

- `()`
Remark:
Deleting columns involves changing ordinal numbers of other columns remaining in the problem object. New ordinal numbers of the remaining columns are assigned under the assumption that the original order of columns is not changed.

Example:
```
> glp::del_cols lp [6, 4, 5];
()```

Copying the whole content of the GLPK problem object to another one

Synopsis:
```
glp::copy_prob destination source names
```

Parameters:
- destination pointer to the destination LP problem object (must already exist)
- source pointer to the source LP problem object
- names one of the following:
  - glp::on copy all symbolic names as well
  - glp::off do not copy the symbolic names

Returns:
```
()
```

Example:
```
> glp::copy_prob lp_dest lp_src glp::on;
()
```

Erasing all data from the GLPK problem object

Synopsis:
```
glp::erase_prob lp
```

Parameters:
- lp pointer to the LP problem object, it remains still valid after the function call

Returns:
```
()
```

Example:
```
> glp::erase_prob lp;
()
```
Delete the GLPK problem object  

Synopsis:

\texttt{glp::delete\_prob \ lp}

Parameters:

\texttt{lp} pointer to the LP problem object, it is not valid any more after the function call

Returns:

()  

Example:

> \texttt{glp::delete\_prob \ lp; (}

Problem retrieving routines  

Get the problem name  

Synopsis:

\texttt{glp::get\_prob\_name \ lp}

Parameters:

\texttt{lp} pointer to the LP problem object

Returns:

name of the problem

Example:

> \texttt{glp::get\_prob\_name \ lp; "Testing problem"}

Get the objective name  

Synopsis:

\texttt{glp::get\_obj\_name \ lp}

Parameters:

\texttt{lp} pointer to the LP problem object

Returns:

name of the objective

Example:

> \texttt{glp::get\_obj\_name \ lp; "Total costs"}
Get the objective direction  Synopsis:

`glp::get_obj_dir lp`

Parameters:

`lp`  pointer to the LP problem object

Returns:

returns one of the following:

`glp::min`  minimize

`glp::max`  maximize

Example:

```
> glp::get_obj_dir lp;
`glp::min`
```

Get number of rows  Synopsis:

`glp::get_num_rows lp`

Parameters:

`lp`  pointer to the LP problem object

Returns:

number of rows (constraints)

Example:

```
> glp::get_num_rows lp;
58
```

Get number of columns  Synopsis:

`glp::get_num_cols lp`

Parameters:

`lp`  pointer to the LP problem object

Returns:

number of columns (structural variables)

Example:

```
> glp::get_num_cols lp;
65
```
Get name of a row  Synopsis:

\texttt{glp::get\_row\_name lp rowindex}

Parameters:

- \texttt{lp}  pointer to the LP problem object
- \texttt{rowindex}  row index

Returns:

- name of the given row

Example:

> \texttt{glp::get\_row\_name lp 3;}

"The third row"

Get name of a column  Synopsis:

\texttt{glp::get\_col\_name lp colindex}

Parameters:

- \texttt{lp}  pointer to the LP problem object
- \texttt{colindex}  column index

Returns:

- name of the given column

Example:

> \texttt{glp::get\_col\_name lp 2;}

"The second column"

Get row type  Synopsis:

\texttt{glp::get\_row\_type lp rowindex}

Parameters:

- \texttt{lp}  pointer to the LP problem object
- \texttt{rowindex}  row index

Returns:

- returns one of the following:
  - \texttt{glp::fr}  free variable
  - \texttt{glp::lo}  variable with lower bound
  - \texttt{glp::up}  variable with upper bound
**glp::db** double bounded variable

**glp::fx** fixed variable

Example:

```c
> glp::get_row_type lp 3;
```

Get row lower bound  

**Synopsis:**

`glp::get_row_lb lp rowindex`

**Parameters:**

- **lp**  pointer to the LP problem object
- **rowindex**  row index

**Returns:**

- the row lower bound; if the row has no lower bound then it returns the smallest double number

Example:

```c
> glp::get_row_lb lp 3;
50.0
```

Get row upper bound  

**Synopsis:**

`glp::get_row_ub lp rowindex`

**Parameters:**

- **lp**  pointer to the LP problem object
- **rowindex**  row index

**Returns:**

- the row upper bound; if the row has no upper bound then it returns the biggest double number

Example:

```c
> glp::get_row_ub lp 3;
150.0
```

Get column type  

**Synopsis:**

`glp::get_col_type lp colindex`

**Parameters:**
lp  pointer to the LP problem object

colindex  column index

Returns:

returns one of the following:

- glp::fr  free variable
- glp::lo  variable with lower bound
- glp::up  variable with upper bound
- glp::db  double bounded variable
- glp::fx  fixed variable

Example:

> glp::get_col_type lp 2;
glp::up

Get column lower bound  Synopsis:

glp::get_col_lb lp colindex

Parameters:

- lp  pointer to the LP problem object
- colindex  column index

Returns:

the column lower bound; if the column has no lower bound then it returns the smallest double number

Example:

> glp::get_col_lb lp 3;
-1.79769313486232e+308

Get column upper bound  Synopsis:

glp::get_col_ub lp colindex

Parameters:

- lp  pointer to the LP problem object
- colindex  column index

Returns:

the column upper bound; if the column has no upper bound then it returns the biggest double number
Example:
> glp::get_col_lb lp 3;
150.0

Get objective coefficient  Synopsis:
glp::get_obj_coef lp colindex

Parameters:
  lp  pointer to the LP problem object
  colindex  column index; zero index denotes the constant term (objective shift)

Returns:
  the coefficient of given column in the objective

Example:
> glp::get_obj_coef lp 3;
5.8

Get number of nonzero coefficients  Synopsis:
glp::get_num_nz lp

Parameters:
  lp  pointer to the LP problem object

Returns:
  number of non-zero coefficients in the problem matrix

Example:
> glp::get_num_nz lp;
158

Retrive a row from the problem matrix  Synopsis:
glp::get_mat_row lp rowindex

Parameters:
  lp  pointer to the LP problem object
  rowindex  row index

Returns:
  non-zero coefficients of the given row in a list form of tuples (colindex, coefficient)
Example:

```cpp
> get_mat_row lp 3;
[[3, 6.0], [2, 2.0], [1, 2.0]]
```

Retrieve a column from the problem matrix  Synopsis:

```cpp
glp::get_mat_col lp colindex
```

Parameters:

- `lp` pointer to the LP problem object
- `colindex` column index

Returns:

- non-zero coefficients of the given column in a list form of tuples (rowindex, coefficient)

Example:

```cpp
> get_mat_col lp 2;
[[3, 2.0], [2, 4.0], [1, 1.0]]
```

Row and column searching routines

Create index for searching rows and columns by their names  Synopsis:

```cpp
glp::create_index lp
```

Parameters:

- `lp` pointer to the LP problem object

Returns:

- ()

Example:

```cpp
> glp::create_index lp;
()
```

Find a row number by name  Synopsis:

```cpp
glp::find_row lp rowname
```

Parameters:

- `lp` pointer to the LP problem object
- `rowname` row name

Returns:
ordinal number (index) of the row

**Remark:**

The search index is automatically created if it does not already exists.

**Example:**

```c
> glp::find_row lp "The third row";
3
```

**Find a column number by name**

**Synopsis:**

```c
glp::find_col lp colname
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colname` column name

**Returns:**

ordinal number (index) of the column

**Remark:**

The search index is automatically created if it does not already exists.

**Example:**

```c
> glp::find_col lp "The second row";
2
```

**Delete index for searching rows and columns by their names**

**Synopsis:**

```c
glp::delete_index lp
```

**Parameters:**

- `lp` pointer to the LP problem object

**Returns:**

()`

**Example:**

```c
> glp::delete_index lp;
()
```

**Problem scaling routines**

**Set the row scale factor**

**Synopsis:**

15.5.1 Basic API routines
glp::set_rii lp (rowindex, coefficient)

Parameters:
   lp  pointer to the LP problem object
   rowindex  row index
   coefficient  scaling coefficient

Returns:
   ()

Example:
> glp::set_rii lp (3, 258.6);
()

Set the column scale factor  Synopsis:

glp::set_sjj lp (colindex, coefficient)

Parameters:
   lp  pointer to the LP problem object
   colindex  column index
   coefficient  scaling coefficient

Returns:
   ()

Example:
> glp::set_sjj lp (2, 12.8);
()

Retrieve the row scale factor  Synopsis:

glp::get_rii lp rowindex

Parameters:
   lp  pointer to the LP problem object
   rowindex  row index

Returns:
   scaling coefficient of given row

Example:
Retrieve the column scale factor

**Synopsis:**

```cpp
glp::get_sjj lp colindex
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colindex` column index

**Returns:**

scaling coefficient of given column

**Example:**

```cpp
> glp::get_sjj lp 2;
12.8
```

Scale the problem data according to supplied flags

**Synopsis:**

```cpp
glp::scale_prob lp flags
```

**Parameters:**

- `lp` pointer to the LP problem object
- `flags` symbolic integer constants which can be combined together by arithmetic or; the possible constants are:
  - `glp::sf_gm` perform geometric mean scaling
  - `glp::sf_eq` perform equilibration scaling
  - `glp::sf_2n` round scale factors to power of two
  - `glp::sf_skip` skip if problem is well scaled
  - `glp::sf_auto` choose scaling options automatically

**Returns:**

()

**Example:**

```cpp
> glp::scale_prob lp (glp::sf_gm || glp::sf_2n);
()```
Unscale the problem data  Synopsis:

```cpp
glp::unscale_prob lp
```

Parameters:

- `lp` pointer to the LP problem object

Returns:

- `()`

Example:

```cpp
> glp::unscale_prob lp;
()```

LP basis constructing routines

Set the row status  Synopsis:

```cpp
glp::set_row_stat lp (rowindex, status)
```

Parameters:

- `lp` pointer to the LP problem object
- `rowindex` row index
- `status` one of the following:

  - `glp::bs` make the row basic (make the constraint inactive)
  - `glp::nl` make the row non-basic (make the constraint active)
  - `glp::nu` make the row non-basic and set it to the upper bound; if the row is not double-bounded, this status is equivalent to `glp::nl` (only in the case of this routine)
  - `glp::nf` the same as `glp::nl` (only in the case of this routine)
  - `glp::ns` the same as `glp::nl` (only in the case of this routine)

Returns:

- `()`

Example:

```cpp
> glp::set_row_stat lp (3, glp::nu);
()```

Set the column status  Synopsis:
glp::set_col_stat lp (colindex, status)

Parameters:

lp  pointer to the LP problem object
colindex  column index
status  one of the following:

  glp::bs  make the column basic
  glp::nl  make the column non-basic
  glp::nu  make the column non-basic and set it to the upper bound; if the column is not double-bounded, this status is equivalent to glp::nl (only in the case of this routine)
  glp::nf  the same as glp::nl (only in the case of this routine)
  glp::ns  the same as glp::nl (only in the case of this routine)

Returns:

()

Example:

> glp::set_col_stat lp (2, glp::bs);
()

Construct standard problem basis  Synopsis:

glp::std_basis lp

Parameters:

lp  pointer to the LP problem object

Returns:

()

Example:

> glp::std_basis lp;
()

Construct advanced problem basis  Synopsis:

glp::adv_basis lp

Parameters:

lp  pointer to the LP problem object
Returns:

()

Example:
> glp::adv_basis lp;
()

Construct Bixby's problem basis

Example:
> glp::cpx_basis lp;
()

Synopsis:

Parameters:

lp  pointer to the LP problem object

Returns:

()

Example:
> glp::cpx_basis lp;
()

Synopsis:

Simplex method routines

Synopsis:

Parameters:

lp  pointer to the LP problem object

options  list of solver options in the form of tuples (option_name, value):

   glp::msg_lev
   (default: glp::msg_all) - message level for terminal output:

   glp::msg_off: no output
   glp::msg_err: error and warning messages only
   glp::msg_on: normal output;
   glp::msg_all: full output (including informational messages)

   glp::meth  (default: glp::primal) - simplex method option
**glp::primal**: use two-phase primal simplex

**glp::dual**: use two-phase dual simplex;

**glp::dualp**: use two-phase dual simplex, and if it fails, switch to the primal simplex

**glp::pricing** (default: glp::pt_pse) - pricing technique

- **glp::pt_std**: standard (textbook)
- **glp::pt_pse**: projected steepest edge

**glp::r_test** (default: glp::rt_har) - ratio test technique

- **glp::rt_std**: standard (textbook)
- **glp::rt_har**: Harris’ two-pass ratio test

**glp::tol_bnd** (default: 1e-7) - tolerance used to check if the basic solution is primal feasible

**glp::tol_dj** (default: 1e-7) - tolerance used to check if the basic solution is dual feasible

**glp::tol_piv** (default: 1e-10) - tolerance used to choose eligible pivotal elements of the simplex table

**glp::obj_ll** (default: -DBL_MAX) - lower limit of the objective function - if the objective function reaches this limit and continues decreasing, the solver terminates the search - used in the dual simplex only

**glp::obj_ul** (default: +DBL_MAX) - upper limit of the objective function. If the objective function reaches this limit and continues increasing, the solver terminates the search - used in the dual simplex only

**glp::it_lim** (default: INT_MAX) - simplex iteration limit

**glp::tm_lim** (default: INT_MAX) - searching time limit, in milliseconds

**glp::out_frq** (default: 200) - output frequency, in iterations - this parameter specifies how frequently the solver sends information about the solution process to the terminal

---

15.5.1 Basic API routines
**glp::out_dly** (default: 0) - output delay, in milliseconds - this parameter specifies how long the solver should delay sending information about the solution process to the terminal

**glp::presolve** (default: glp::off) - LP presolver option:

- **glp::on**: enable using the LP presolver
- **glp::off**: disable using the LP presolver

**Returns:**

one of the following:

- **glp::ok**: the LP problem instance has been successfully solved; this code does not necessarily mean that the solver has found optimal solution, it only means that the solution process was successful
- **glp::ebadb**: unable to start the search, because the initial basis specified in the problem object is invalid - the number of basic (auxiliary and structural) variables is not the same as the number of rows in the problem object
- **glp::esing**: unable to start the search, because the basis matrix corresponding to the initial basis is singular within the working precision
- **glp::econd**: unable to start the search, because the basis matrix corresponding to the initial basis is ill-conditioned, i.e. its condition number is too large
- **glp::ebound**: unable to start the search, because some double-bounded (auxiliary or structural) variables have incorrect bounds
- **glp::efail**: the search was prematurely terminated due to the solver failure
- **glp::eobjll**: the search was prematurely terminated, because the objective function being maximized has reached its lower limit and continues decreasing (the dual simplex only)
- **glp::eobjul**: the search was prematurely terminated, because the objective function being minimized has reached its upper limit and continues increasing (the dual simplex only)
- **glp::eitlim**: the search was prematurely terminated, because the simplex iteration limit has been exceeded
- **glp::etmlim**: the search was prematurely terminated, because the time limit has been exceeded
**glp::enopfs** the LP problem instance has no primal feasible solution  
(only if the LP presolver is used)

**glp::enodfs** the LP problem instance has no dual feasible solution  
(only if the LP presolver is used)

When the list of options contains some bad option(s) then a list of bad options is returned instead.

**Remark:**
Options not mentioned in the option list are set to their default values.

**Example:**

```
> glp::simplex lp [(glp::presolve, glp::on), (glp::msg_lev, glp::msg_all)];
```

```
lp::simplex: original LP has 3 rows, 3 columns, 9 non-zeros  
lp::simplex: presolved LP has 3 rows, 3 columns, 9 non-zeros  
Scaling...
  A: min|aij| = 1,000e+000 max|aij| = 1,000e+001 ratio = 1,000e+001  
Problem data seem to be well scaled
Crashing...
  Size of triangular part = 3
  *  0: obj = 0,000000000e+000  infeas = 0,000e+000 (0)
  *  2: obj = 7,333333333e+002  infeas = 0,000e+000 (0)
Optimal solution found
lp::ok
```

Solve the LP problem using simplex method in exact arithmetics

**Synopsis:**

```
lp::exact lp options
```

**Parameters:**

- **lp** pointer to the LP problem object
- **options** list of solver options in the form of tuples (option_name, value):
  - **glp::it_lim** (default: INT_MAX) - simplex iteration limit
  - **glp::tm lim** (default: INT_MAX) - searching time limit, in milliseconds

**Returns:**

one of the following:

- **glp::ok** the LP problem instance has been successfully solved; this code does not necessarily mean that the solver has found optimal solution, it only means that the solution process was successful
- **glp::ebadb** unable to start the search, because the initial basis specified in the problem object is invalid - the number of basic (auxiliary and
structural) variables is not the same as the number of rows in the problem object

**glp::esing** unable to start the search, because the basis matrix corresponding to the initial basis is singular within the working precision

**glp::ebound** unable to start the search, because some double-bounded (auxiliary or structural) variables have incorrect bounds

**glp::efail** the search was prematurely terminated due to the solver failure

**glp::eitlim** the search was prematurely terminated, because the simplex iteration limit has been exceeded

**glp::etmlim** the search was prematurely terminated, because the time limit has been exceeded

When the list of options contains some bad option(s) then a list of bad options is returned instead.

**Remark:**

Options not mentioned in the option list are set to their default values.

**Example:**

```cpp
> glp::exact lp [];
glp::exact: 3 rows, 3 columns, 9 non-zeros
GNU MP bignum library is being used
* 2: objval = 0 (0)
* 4: objval = 733,333333333333 (0)
OPTIMAL SOLUTION FOUND

glp::ok
```

**Retrieve generic status of basic solution**  
**Synopsis:**

`glp::get_status lp`

**Parameters:**

- **lp** pointer to the LP problem object

**Returns:**

one of the following:

**glp::undef** solution is undefined

**glp::feas** solution is feasible

**glp::infeas** solution is infeasible

**glp::nofeas** no feasible solution exists
glp::opt  solution is optimal

glp::unbnd  solution is unbounded

Example:

> glp::get_status lp;
glp::opt

Retrieve generic status of primal solution  Synopsis:

glp::get_prim_stat lp

Parameters:

lp  pointer to the LP problem object

Returns:

one of the following:

  glp::undef  primal solution is undefined
  glp::feas  primal solution is feasible
  glp::infeas  primal solution is infeasible
  glp::nofeas  no primal feasible solution exists

Example:

> glp::get_prim_stat lp;
glp::feas

Retrieve generic status of dual solution  Synopsis:

glp::get_dual_stat lp

Parameters:

lp  pointer to the LP problem object

Returns:

one of the following:

  glp::undef  dual solution is undefined
  glp::feas  dual solution is feasible
  glp::infeas  dual solution is infeasible
  glp::nofeas  no dual feasible solution exists

Example:
> glp::get_dual_stat lp;
glp::feas

Retrieve value of the objective function  Synopsis:
glp::get_obj_val lp

Parameters:
   lp  pointer to the LP problem object

Returns:
   value of the objective function

Example:
> glp::get_obj_val lp
733.333333333333

Retrieve generic status of a row variable  Synopsis:
glp::get_row_stat lp rowindex

Parameters:
   lp  pointer to the LP problem object
   rowindex  row index

Returns:
   one of the following:
      glp::bs  basic variable
      glp::nl  non-basic variable on its lower bound
      glp::nu  non-basic variable on its upper bound
      glp::nf  non-basic free (unbounded) variable
      glp::ns  non-basic fixed variable

Example:
> glp::get_row_stat lp 3;
glp::bs

Retrieve row primal value

Synopsis:  glp::get_row_prim lp rowindex

Parameters:
   lp  pointer to the LP problem object
rowindex row index

Returns:

primal value of the row (auxiliary) variable

Example:

```cpp
> glp::get_row_prim lp 3;
200.0
```

Retrieve row dual value  Synopsis:

glp::get_row_dual lp rowindex

Parameters:

lp pointer to the LP problem object
rowindex row index

Returns:

dual value of the row (auxiliary) variable

Example:

```cpp
> glp::get_row_dual lp 3;
0.0
```

Retrieve generic status of a column variable  Synopsis:

glp::get_col_stat lp colindex

Parameters:

lp pointer to the LP problem object
colindex column index

Returns:

one of the following:

- glp::bs basic variable
- glp::nl non-basic variable on its lower bound
- glp::nu non-basic variable on its upper bound
- glp::nf non-basic free (unbounded) variable
- glp::ns non-basic fixed variable

Example:
Retrieve column primal value  

**Synopsis:**

```cpp
glp::get_col_prim lp colindex
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colindex` column index

**Returns:**

primal value of the column (structural) variable

**Example:**

```cpp
> glp::get_col_prim lp 2;
66.6666666666667
```

Retrieve column dual value  

**Synopsis:**

```cpp
glp::get_col_dual lp colindex
```

**Parameters:**

- `lp` pointer to the LP problem object
- `colindex` column index

**Returns:**

dual value of the column (structural) variable

**Example:**

```cpp
> glp::get_col_dual lp 2;
0.0
```

Determine variable causing unboundedness  

**Synopsis:**

```cpp
glp::get_unbnd_ray lp
```

**Parameters:**

- `lp` pointer to the LP problem object

**Returns:**

The routine `glp_get_unbnd_ray` returns the number $k$ of a variable, which causes primal or dual unboundedness. If $1 \leq k \leq m$, it is $k$-th auxiliary variable, and if $m + 1 \leq k \leq m + n$, it is $(k - m)$-th structural variable, where $m$ is the number

---

502  

15.5 Descriptions of interface functions
of rows, n is the number of columns in the problem object. If such variable is not defined, the routine returns 0.

Remark:
If it is not exactly known which version of the simplex solver detected unboundedness, i.e. whether the unboundedness is primal or dual, it is sufficient to check the status of the variable with the routine glp::get_row_stat or glp::get_col_stat. If the variable is non-basic, the unboundedness is primal, otherwise, if the variable is basic, the unboundedness is dual (the latter case means that the problem has no primal feasible solution).

Example:
> glp::get_unbnd_ray lp;
0

Interior-point method routines

Solve the LP problem using interior-point method  Synopsis:
glp::interior lp options

Parameters:

lp  pointer to the LP problem object

options list of solver options in the form of tuples (option_name, value):

  glp::msg_lev
    (default: glp::msg_all) - message level for terminal output:
    
    glp::msg_off: no output
    glp::msg_err: error and warning messages only
    glp::msg_on: normal output;
    glp::msg_all: full output (including informational messages)

  glp::ord_alg (default: glp::ord_amd) - ordering algorithm option
    
    glp::ord_none: use natural (original) ordering
    glp::ord_qmd: quotient minimum degree (QMD)
    glp::ord_amd: approximate minimum degree (AMD)
**glp::ord_sysamd**: approximate minimum degree (SYSAMD)

Returns:

one of the following:

- **glp::ok** the LP problem instance has been successfully solved; this code does not necessarily mean that the solver has found optimal solution, it only means that the solution process was successful
- **glp::efail** the problem has no rows/columns
- **glp::enocvg** very slow convergence or divergence
- **glp::eitlim** iteration limit exceeded
- **glp::einstab** numerical instability on solving Newtonian system

**Example:**

```plaintext
> glp::interior lp [{glp::ord_alg, glp::ord.amd}];
Original LP has 3 row(s), 3 column(s), and 9 non-zero(s)
Working LP has 3 row(s), 6 column(s), and 12 non-zero(s)
Matrix A has 12 non-zeros
Matrix S = A*A' has 6 non-zeros (upper triangle)
Approximate minimum degree ordering (AMD)...
Computing Cholesky factorization S = L*L'...
Matrix L has 6 non-zeros
Guessing initial point...
Optimization begins...

OPTIMAL SOLUTION FOUND
```

**Retrieve status of interior-point solution**

**Synopsis:**

```plaintext
glp::ipt_status lp
```

**Parameters:**

- **lp** pointer to the LP problem object
Returns:

one of the following

- `glp::undef` interior-point solution is undefined
- `glp::opt` interior-point solution is optimal
- `glp::infeas` interior-point solution is infeasible
- `glp::nofeas` no feasible primal-dual solution exists

Example:

```c
> glp::ipt_status lp;
glp::opt
```

Retrieve the objective function value of interior-point solution  

Synopsis:

`glp::ipt_obj_val lp`

Parameters:

- `lp` pointer to the LP problem object

Returns:

- objective function value of interior-point solution

Example:

```c
> glp::ipt_obj_val lp;
733.33332295849
```

Retrieve row primal value of interior-point solution  

Synopsis:

`glp::ipt_row_prim lp rowindex`

Parameters:

- `lp` pointer to the LP problem object
- `rowindex` row index

Returns:

- primal value of the row (auxiliary) variable

Example:

```c
> glp::ipt_row_prim lp 3;
200.000000920688
```
Retrieve row dual value of interior-point solution  

Synopsis:

```cpp
glp::ipt_row_dual lp rowindex
```

Parameters:

- `lp` pointer to the LP problem object
- `rowindex` row index

Returns:

dual value of the row (auxiliary) variable

Example:

```cpp
> glp::ipt_row_dual lp 3;
2.50607466186742e-008
```

Retrieve column primal value of interior-point solution  

Synopsis:

```cpp
glp::ipt_col_prim lp colindex
```

Parameters:

- `lp` pointer to the LP problem object
- `colindex` column index

Returns:

primal value of the column (structural) variable

Example:

```cpp
> glp::ipt_col_prim lp 2;
66.666666406779
```

Retrieve column dual value of interior-point solution  

Synopsis:

```cpp
glp::ipt_col_dual lp colindex
```

Parameters:

- `lp` pointer to the LP problem object
- `colindex` column index

Returns:

dual value of the column (structural) variable

Example:

```cpp
> glp::ipt_col_dual lp 2;
2.00019467655466e-009
```
Mixed integer programming routines

Set column kind  Synopsis:

\[ \text{glp::set_col_kind \ lp (colindex, colkind)} \]

Parameters:

- \( \text{lp} \) pointer to the LP problem object
- \( \text{colindex} \) column index
- \( \text{colkind} \) column kind - one of the following:
  - \( \text{glp::cv} \) continuous variable
  - \( \text{glp::iv} \) integer variable
  - \( \text{glp::bv} \) binary variable

Returns:

- ()

Example:

\[ > \text{glp::set_col_kind \ lp (1, glp::iv)}; \]

Retrieval column kind  Synopsis:

\[ \text{glp::get_col_kind \ lp \ colindex} \]

Parameters:

- \( \text{lp} \) pointer to the LP problem object
- \( \text{colindex} \) column index

Returns:

- one of the following:
  - \( \text{glp::cv} \) continuous variable
  - \( \text{glp::iv} \) integer variable
  - \( \text{glp::bv} \) binary variable

Example:

\[ > \text{glp::get_col_kind \ lp 1}; \]

\[ \text{glp::iv} \]
Retrieve number of integer columns  Synopsis:

\texttt{glp::get_num_int \textit{lp}}

\textbf{Parameters:}

\textit{lp}  pointer to the LP problem object

\textbf{Returns:}

number of integer columns (including binary columns)

\textbf{Example:}

```cpp
> \texttt{glp::get_num_int \textit{lp};}
1
```

Retrieve number of binary columns  Synopsis:

\texttt{glp::get_num_bin \textit{lp}}

\textbf{Parameters:}

\textit{lp}  pointer to the LP problem object

\textbf{Returns:}

number of binary columns

\textbf{Example:}

```cpp
> \texttt{glp::get_num_bin \textit{lp}}
0
```

Solve the MIP problem using branch-and-cut method  Synopsis:

\texttt{glp::intopt \textit{lp} \textit{options}}

\textbf{Parameters:}

\textit{lp}  pointer to the LP problem object

\textit{options}  list of solver options in the form of tuples (\textit{option\_name}, \textit{value}):

\texttt{glp::msg\_lev}

\texttt{(default: glp::msg\_all) - message level for terminal output:}

\texttt{glp::msg\_off: no output}

\texttt{glp::msg\_err: error and warning messages only}

\texttt{glp::msg\_on: normal output;}

---

508  15.5 Descriptions of interface functions
**glp::msg_all**: full output (including informational messages)

**glp::br_tech** (default: glp::bt::blb) - branching technique

- **glp::br_ffv**: first fractional variable
- **glp::br_lfv**: last fractional variable
- **glp::br_mfv**: most fractional variable
- **glp::br_dth**: heuristic by Driebeck and Tomlin
- **glp::br_pch**: hybrid pseudocost heuristic

**glp::bt_tech** (default: glp::pt::pse) - backtracking technique

- **glp::bt_dfs**: depth first search;
- **glp::bt_bfs**: breadth first search;
- **glp::bt_blb**: best local bound;
- **glp::bt_bph**: best projection heuristic.

**glp::pp_tech** (default: glp::pp::all) - preprocessing technique

- **glp::pp_none**: disable preprocessing;
- **glp::pp_root**: perform preprocessing only on the root level
- **glp::pp_all**: perform preprocessing on all levels

**glp::fp_heur** (default: glp::off) - feasibility pump heuristic:

- **glp::on**: enable applying the feasibility pump heuristic
- **glp::off**: disable applying the feasibility pump heuristic

**glp::gmi_cuts**

(default: glp::off) - Gomory’s mixed integer cuts:

---

15.5.1 Basic API routines
\texttt{glp::on}: enable generating Gomory’s cuts;
\texttt{glp::off}: disable generating Gomory’s cuts.

\texttt{glp::mir_cuts}

(default: \texttt{glp::off}) - mixed integer rounding (MIR) cuts:

\texttt{glp::on}: enable generating MIR cuts;
\texttt{glp::off}: disable generating MIR cuts.

\texttt{glp::cov_cuts} (default: \texttt{glp::off}) - mixed cover cuts:

\texttt{glp::on}: enable generating mixed cover cuts;
\texttt{glp::off}: disable generating mixed cover cuts.

\texttt{glp::clq_cuts} (default \texttt{glp::off}) - clique cuts:

\texttt{glp::on}: enable generating clique cuts;
\texttt{glp::off}: disable generating clique cuts.

\texttt{glp::tol_int} (default: \texttt{1e-5}) - absolute tolerance used to check if optimal solution to the current LP relaxation is integer feasible

\texttt{glp::tol_obj} (default: \texttt{1e-7}) - relative tolerance used to check if the objective value in optimal solution to the current LP relaxation is not better than in the best known integer feasible solution

\texttt{glp::mip_gap} (default: \texttt{0.0}) - the relative mip gap tolerance; if the relative mip gap for currently known best integer feasible solution falls below this tolerance, the solver terminates the search - this allows obtaining sub-optimal integer feasible solutions if solving the problem to optimality takes too long time

\texttt{glp::tm_lim} (default: \texttt{INT\_MAX}) - searching time limit, in milliseconds

15.5 Descriptions of interface functions
glp::out_freq (default: 5000) - output frequency, in milliseconds - this parameter specifies how frequently the solver sends information about the solution process to the terminal.

glp::out_dly (default: 10000) - output delay, in milliseconds - this parameter specifies how long the solver should delay sending information about the solution of the current LP relaxation with the simplex method to the terminal.

glp::cb_func

(default: glp::off) - specifies whether to use the user-defined callback routine

- **glp::on**: use user-defined callback function - the function glp::mip_cb tree info must be defined by the user
- **glp::off**: do not use user-defined callback function

glp::cb_info (default: NULL) - transit pointer passed to the routine glp::mip_cb tree info (see above)

glp::cb_size (default: 0) - the number of extra (up to 256) bytes allocated for each node of the branch-and-bound tree to store application-specific data - on creating a node these bytes are initialized by binary zeros.

**glp::presolve** (default: glp::off) - LP presolver option:

- **glp::on**: enable using the MIP presolver
- **glp::off**: disable using the MIP presolver

**glp::binarize**

=default: glp::off) - binarization (used only if the presolver is enabled):

- **glp::on**: replace general integer variables by binary ones
- **glp::off**: do not use binarization

Returns:
one of the following:

- `glp::ok` the MIP problem instance has been successfully solved; this code does not necessarily mean that the solver has found optimal solution, it only means that the solution process was successful.

- `glp::ebound` unable to start the search, because some double-bounded (auxiliary or structural) variables have incorrect bounds or some integer variables have non-integer (fractional) bounds.

- `glp::eroot` unable to start the search, because optimal basis for initial LP relaxation is not provided - this code may appear only if the presolver is disabled.

- `glp::enopfs` unable to start the search, because LP relaxation of the MIP problem instance has no primal feasible solution - this code may appear only if the presolver is enabled.

- `glp::enodfs` unable to start the search, because LP relaxation of the MIP problem instance has no dual feasible solution; in other word, this code means that if the LP relaxation has at least one primal feasible solution, its optimal solution is unbounded, so if the MIP problem has at least one integer feasible solution, its (integer) optimal solution is also unbounded - this code may appear only if the presolver is enabled.

- `glp::efail` the search was prematurely terminated due to the solver failure.

- `glp::emipgap` the search was prematurely terminated, because the relative mip gap tolerance has been reached.

- `glp::etmlim` the search was prematurely terminated, because the time limit has been exceeded.

- `glp::estop` the search was prematurely terminated by application - this code may appear only if the advanced solver interface is used.

When the list of options contains some bad option(s) then a list of bad options is returned instead.

**Remark:**

Options not mentioned in the option list are set to their default values.

**Example:**

```c
> glp::intopt lp [(glp::presolve, glp::on)];
ipp_basic_tech: 0 row(s) and 0 column(s) removed
ipp_reduce_bnds: 2 pass(es) made, 3 bound(s) reduced
ipp_basic_tech: 0 row(s) and 0 column(s) removed
ipp_reduce_coef: 1 pass(es) made, 0 coefficient(s) reduced
glp_intopt: presolved MIP has 3 rows, 3 columns, 9 non-zeros
glp_intopt: 3 integer columns, none of which are binary
```
Scaling...

INTEGER OPTIMAL SOLUTION FOUND

Retrieve status of mip solution  Synopsis:
glp::mip_status lp

Parameters:

lp  pointer to the LP problem object

Returns:

one of the following:

  glp::undef  MIP solution is undefined
  glp::opt   MIP solution is integer optimal
  glp::feas  MIP solution is integer feasible, however, its optimality (or
                     non-optimality) has not been proven, perhaps due to premature
                     termination of the search
  glp::nofeas problem has no integer feasible solution (proven by the
                      solver)

Example:
> glp::mip_status lp;
glp::opt

Retrieve the objective function value of mip solution  Synopsis:
glp::mip_obj_val lp

Parameters:

lp  pointer to the LP problem object

Returns:
objective function value of mip solution

Example:
> glp::mip_obj_val lp;
732.0

Retrieve row value of mip solution  Synopsis:
glp::mip_row_val lp rowindex

Parameters:
  lp  pointer to the LP problem object
  rowindex  row index

Returns:
  row value (value of auxiliary variable)

Example:
> glp::mip_row_val lp 3;
200.0

Retrieve column value of mip solution  Synopsis:
glp::mip_col_val lp colindex

Parameters:
  lp  pointer to the LP problem object
  colindex  column index

Returns:
  column value (value of structural variable)

Example:
> glp::mip_col_val lp 2;
67.0

Additional routines

Check Karush-Kuhn-Tucker conditions  Synopsis:
glp::check_kkt lp solution condition

Parameters:
  lp  pointer to the LP problem object
  solution  one of the following
Pure Language and Library Documentation, Release 0.68

glp::sol check basic solution

glp::ipt check interior-point solution

glp::mip check mixed integer solution

Condition one of the following

glp::kkt_pe check primal equality constraints

glp::kkt_pb check primal bound constraints

glp::kkt_de check dual equality constraints (not available for MIP)

glp::kkt_db check dual bound constraints (not available for MIP)

Returns:

tuple with four members (ae_max, ae_ind, re_max, re_ind) where the variables indicate:

ae_max largest absolute error

ae_ind number of row (kkt_pe), column (kkt_de), or variable (kkt_pb, kkt_db) with the largest absolute error

re_max largest relative error

re_ind number of row (kkt_pe), column (kkt_de), or variable (kkt_pb, kkt_db) with the largest relative error

where the variable index is (1 <= k <= m) for auxiliary variable and (m+1 <= k <= m+n) for structural variable

Example:

> glp::check_kkt lp glp::sol glp::kkt_pe;
0.0,0,0,0

> glp::check_kkt lp glp::mip glp::kkt_pe;
2.23517417907715e-008,1,7.50126764193079e-016,34169

15.5.2 Utility API routines

Problem data reading/writing routines

Read LP problem data from a MPS file

Synopsis:

glp::read_mps lp format filename

Parameters:

lp pointer to the LP problem object

format one of the following

15.5.2 Utility API routines 515
glp::mps_deck  fixed (ancient) MPS file format

glp::mps_file  free (modern) MPS file format

**filename**  file name - if the file name ends with suffix `.gz`, the file is assumed to be compressed, in which case the routine glp::read_mps decompresses it "on the fly"

**Returns:**

0 if reading went OK; non-zero in case of an error

**Example:**

```cpp
> glp::read_mps lp glp::mps_deck "examples/plan.mps";
```

Reading problem data from ‘examples/plan.mps’...

Problem PLAN
Objective R0000000
8 rows, 7 columns, 55 non-zeros
63 records were read
0

### Write LP problem data into a MPS file  Synopsis:

**glp::write_mps lp format filename**

**Parameters:**

- **lp**  pointer to the LP problem object
- **format**  one of the following
  - **glp::mps_deck**  fixed (ancient) MPS file format
  - **glp::mps_file**  free (modern) MPS file format
- **filename**  file name - if the file name ends with suffix `.gz`, the file is assumed to be compressed, in which case the routine glp_write_mps performs automatic compression on writing it

**Returns:**

0 if writing went OK; non-zero in case of an error

**Example:**

```cpp
> glp::write_mps lp glp::mps_file "examples/plan1.mps";
```

Writing problem data to ‘examples/plan1.mps’...

63 records were written
0

### Read LP problem data from a CPLEX file  Synopsis:

**glp::read_lp lp filename**

**Parameters:**
lp  pointer to the LP problem object

filename  file name - if the file name ends with suffix .gz, the file is assumed to be compressed, in which case the routine glp::read_lp decompresses it “on the fly”

Returns:

0 if writing went OK; non-zero in case of an error

Example:

> glp::read_lp lp "examples/plan.lp";
reading problem data from ‘examples/plan.lp’...
8 rows, 7 columns, 48 non-zeros
39 lines were read
0

Write LP problem data into a CPLEX file  Synopsis:

glp::write_lp lp filename

Parameters:

lp  pointer to the LP problem object

filename  file name - if the file name ends with suffix .gz, the file is assumed to be compressed, in which case the routine glp::write_lp performs automatic compression on writing it

Returns:

0 if writing went OK; non-zero in case of an error

Example:

> glp::write_lp lp "examples/plan1.lp";
writing problem data to ‘examples/plan1.lp’...
29 lines were written
0

Read LP problem data in GLPK format  Synopsis:

glp::read_prob lp filename

Parameters:

lp  pointer to the LP problem object

filename  file name - if the file name ends with suffix .gz, the file is assumed to be compressed, in which case the routine glp::read_prob decompresses it “on the fly”

Returns:
0 if writing went OK; non-zero in case of an error

Example:

```c
> glp::read_prob lp "examples/plan.glpk"
reading problem data from 'examples/plan.glpk'...
8 rows, 7 columns, 48 non-zeros
86 lines were read
0
```

Write LP problem data in GLPK format

**Synopsis:**

`glp::write_prob lp filename`

**Parameters:**

- `lp` pointer to the LP problem object
- `filename` file name - if the file name ends with suffix `.gz`, the file is assumed to be compressed, in which case the routine `glp::write_prob` performs automatic compression on writing it

**Returns:**

0 if writing went OK; non-zero in case of an error

Example:

```c
> glp::write_prob lp "examples/plan1.glpk"
writing problem data to 'examples/plan1.glpk'...
86 lines were written
0
```

Routines for MathProg models

Create the MathProg translator object

**Synopsis:**

`glp::mpl_alloc_wksp`

**Parameters:**

none

**Returns:**

pointer to the MathProg translator object

Example:

```c
> let mpt = glp::mpl_alloc_wksp;
> mpt;
#<pointer 0xa0d0180>
```
Read and translate model section  

Synopsis: 

\[
\text{glp::mpl\_read\_model \ tranobject \ filename \ skip}
\]

Parameters: 

- \text{tranobject}  \quad \text{pointer to the MathProg translator object}
- \text{filename}  \quad \text{file name}
- \text{skip}  \quad \text{if 0 then the data section from the model file is read; if non-zero, the data section in the data model is skipped}

Returns: 

- 0 if reading went OK; non-zero in case of an error

Example: 

```
> mpl\_read\_model mpt "examples/sudoku.mod" 1;
Reading model section from examples/sudoku.mod...
examples/sudoku.mod:69: warning: data section ignored
69 lines were read
0
```

Read and translate data section  

Synopsis: 

\[
\text{glp::mpl\_read\_data \ tranobject \ filename}
\]

Parameters: 

- \text{tranobject}  \quad \text{pointer to the MathProg translator object}
- \text{filename}  \quad \text{file name}

Returns: 

- 0 if reading went OK; non-zero in case of an error

Example: 

```
> glp::mpl\_read\_data mpt "examples/sudoku.dat";
Reading data section from examples/sudoku.dat...
16 lines were read
0
```

Generate the model  

Synopsis: 

\[
\text{glp::mpl\_generate \ tranobject \ filename}
\]

Parameters: 

- \text{tranobject}  \quad \text{pointer to the MathProg translator object}
- \text{filename}  \quad \text{file name}
Returns:

0 if generating went OK; non-zero in case of an error

Example:

```cpp
> glp::mpl_generate mpt "examples/sudoku.lst";
Generating fa...
Generating fb...
Generating fc...
Generating fd...
Generating fe...
Model has been successfully generated
0
```

Build problem instance from the model  

**Synopsis:**

```cpp
glp::mpl_build_prob tranobject lp
```

**Parameters:**

- `tranobject` pointer to the MathProg translator object
- `lp` pointer to the LP problem object

**Returns:**

()  

**Example:**

```cpp
> glp::mpl_build_prob mpt lp;
()
```

Postsolve the model  

**Synopsis:**

```cpp
glp::mpl_postsolve tran lp solution
```

**Parameters:**

- `tranobject` pointer to the MathProg translator object
- `lp` pointer to the LP problem object
- `solution` one of the following:
  - `glp::sol` use the basic solution
  - `glp::ipt` use the interior-point solution
  - `glp::mip` use mixed integer solution

**Returns:**

0 if postsolve went OK; non-zero in case of an error
Example:

> glp::mpl_postsolve mpt lp glp::sol;
> Model has been successfully processed
> 0

Delete the MathProg translator object  Synopsis:

glp::mpl_free_wksp tranobject

Parameters:
  tranobject  pointer to the MathProg translator object

Returns:
  ()

Example:

> glp::mpl_free_wksp mpt;
> ()

Problem solution reading/writing routines

Write basic solution in printable format  Synopsis:

glp::print_sol lp filename

Parameters:
  lp  pointer to the LP problem object
  filename  file name

Returns:
  0 if writing went OK; non-zero in case of an error

Example:

> glp::print_sol lp "examples/test.txt";
> Writing basic solution to ‘examples/test.txt’...
> 0

Read basic solution from a text file  Synopsis:

glp::read_sol lp filename

Parameters:
  lp  pointer to the LP problem object
  filename  file name

Returns:
0 if reading went OK; non-zero in case of an error

Example:

```c
> glp::read_sol lp "examples/test.txt";
Reading basic solution from 'examples/test.txt'...
1235 lines were read 0
```

Write basic solution into a text file  

Synopsis:

```
glp::write_sol lp filename
```

Parameters:

- `lp` pointer to the LP problem object
- `filename` file name

Returns:

0 if writing went OK; non-zero in case of an error

Example:

```c
> glp::write_sol lp "examples/test.txt";
Writing basic solution to 'examples/test.txt'...
1235 lines were written 0
```

Print sensitivity analysis report  

Synopsis:

```
glp::print_ranges lp indices filename
```

Parameters:

- `lp` pointer to the LP problem object
- `indices` list indices $k$ of rows and columns to be included in the report. If $1 \leq k \leq m$, the basic variable is $k$-th auxiliary variable, and if $m + 1 \leq k \leq m + n$, the non-basic variable is $(k - m)$-th structural variable, where $m$ is the number of rows and $n$ is the number of columns in the specified problem object. An empty lists means printing report for all rows and columns.
- `filename` file name

Returns:

0 if the operation was successful

non-zero if the operation failed

Example:
> glp::print_ranges lp [] "sensitivity.rpt";
Write sensitivity analysis report to ‘sensitivity.rpt’...
0

**Write interior-point solution in printable format**

**Synopsis:**

```
glp::print_ipt lp filename
```

**Parameters:**

- `lp` pointer to the LP problem object
- `filename` file name

**Returns:**

0 if writing went OK; non-zero in case of an error

**Example:**

```
> glp::print_ipt lp "examples/test.txt";
Writing interior-point solution to ‘examples/test.txt’...
0
```

**Read interior-point solution from a text file**

**Synopsis:**

```
glp::read_ipt lp filename
```

**Parameters:**

- `lp` pointer to the LP problem object
- `filename` file name

**Returns:**

0 if reading went OK; non-zero in case of an error

**Example:**

```
> glp::read_ipt lp "examples/test.txt";
Reading interior-point solution from ‘examples/test.txt’...
1235 lines were read
0
```

**Write interior-point solution into a text file**

**Synopsis:**

```
glp::write_ipt lp filename
```

**Parameters:**

- `lp` pointer to the LP problem object
- `filename` file name
Returns:

0 if writing went OK; non-zero in case of an error

Example:

```>
glp::write_ipt lp "examples/test.txt";
Writing interior-point solution to 'examples/test.txt'...
1235 lines were written
0
```

Write MIP solution in printable format  Synopsis:

```
            glp::print_mip lp filename
```

Parameters:

- lp  pointer to the LP problem object
- filename  file name

Returns:

0 if writing went OK; non-zero in case of an error

Example:

```>
glp::print_mip lp "examples/test.txt";
Writing MIP solution to 'examples/test.txt'...
0
```

Read MIP solution from a text file  Synopsis:

```
            glp::read_mip lp filename
```

Parameters:

- lp  pointer to the LP problem object
- filename  file name

Returns:

0 if reading went OK; non-zero in case of an error

Example:

```>
glp::read_mip lp "examples/test.txt";
Reading MIP solution from 'examples/test.txt'...
1235 lines were read
0
```

Write MIP solution into a text file  Synopsis:
glp::write_mip lp filename

Parameters:

lp  pointer to the LP problem object
filename  file name

Returns:

0 if writing went OK; non-zero in case of an error

Example:

> glp::write_mip lp "examples/test.txt";
Writing MIP solution to 'examples/test.txt'...
1235 lines were written
0

15.5.3 Advanced API routines

LP basis routines

Check whether basis factorization exists  Synopsis:

glp::bf_exists lp

Parameters:

lp  pointer to the LP problem object

Returns:

non-zero  the basis factorization exists and can be used for calculations
0  the basis factorization does not exist

Example:

> glp::bf:exists lp;
1

Compute the basis factorization  Synopsis:

glp::factorize lp

Parameters:

lp  pointer to the LP problem object

Returns:

one of the following:

glp::ok  the basis factorization has been successfully computed
**glp::ebadb** the basis matrix is invalid, because the number of basic (auxiliary and structural) variables is not the same as the number of rows in the problem object

**glp::esing** the basis matrix is singular within the working precision

**glp::exond** the basis matrix is ill-conditioned, i.e. its condition number is too large

Example:

```c
> glp::factorize lp;
glp::ok
```

**Check whether basis factorization has been updated**  
**Synopsis:**

```c
glp::bf_updated lp
```

**Parameters:**

- `lp` pointer to the LP problem object

**Returns:**

- `0` if the basis factorization has been just computed from “scratch”
- non-zero if the factorization has been updated at least once

Example:

```c
> glp::bf_updated lp;
0
```

**Get basis factorization parameters**  
**Synopsis:**

```c
glp::get_bfcp lp
```

**Parameters:**

- `lp` pointer to the LP problem object

**Returns:**

- complete list of options in a form of tuples (option_name, value):
  - **glp::fact_type** basis factorization type:
    - **glp::bf_ft** LU + Forrest–Tomlin update
    - **glp::bf_bg** LU + Schur complement + Bartels–Golub update
    - **glp::bf_gr** LU + Schur complement + Givens rotation update
**glp::lu_size** the initial size of the Sparse Vector Area, in non-zeros, used on computing LU-factorization of the basis matrix for the first time - if this parameter is set to 0, the initial SVA size is determined automatically

**glp::piv_tol** threshold pivoting (Markowitz) tolerance, $0 < \text{piv} \_\text{tol} < 1$, used on computing LU-factorization of the basis matrix

**glp::piv_lim** this parameter is used on computing LU-factorization of the basis matrix and specifies how many pivot candidates needs to be considered on choosing a pivot element, $\text{piv} \_\text{lim} \geq 1$

**glp::suhl** this parameter is used on computing LU-factorization of the basis matrix

- **glp::on** enables applying the heuristic proposed by Uwe Suhl
- **glp::off** disables this heuristic

**glp::eps_tol** epsilon tolerance, $\text{eps} \_\text{tol} \geq 0$, used on computing LU-factorization of the basis matrix

**glp::max_gro** maximal growth of elements of factor $U$, $\text{max} \_\text{gro} \geq 1$, allowable on computing LU-factorization of the basis matrix

**glp::nfs_max** maximal number of additional row-like factors (entries of the eta file), $\text{nfs} \_\text{max} \geq 1$, which can be added to LU-factorization of the basis matrix on updating it with the Forrest–Tomlin technique

**glp::upd_tol** update tolerance, $0 < \text{upd} \_\text{tol} < 1$, used on updating LU-factorization of the basis matrix with the Forrest–Tomlin technique

**glp::nrs_max** maximal number of additional rows and columns, $\text{nrs} \_\text{max} \geq 1$, which can be added to LU-factorization of the basis matrix on updating it with the Schur complement technique

**glp::rs_size** the initial size of the Sparse Vector Area, in non-zeros, used to store non-zero elements of additional rows and columns introduced on updating LU-factorization of the basis matrix with the Schur complement technique - if this parameter is set to 0, the initial SVA size is determined automatically

**Example:**

```c
> glp::get_bfcp lp;
[(glp::fact_type,glp::bf_ft),(glp::lu_size,0),(glp::piv_tol,0.1),
 (glp::piv_lim,4), (glp::suhl,glp::on), (glp::eps_tol,1e-15),
 (glp::max_gro,10000000000.0), (glp::nfs_max,50), (glp::upd_tol,1e-06),
 (glp::nrs_max,50), (glp::rs_size,0)]
```

**Change basis factorization parameters**  
### Synopsis:

15.5.3 Advanced API routines 527
glp::set_bfcp lp options

Parameters:

lp  pointer to the LP problem object

options  list of options in a form of tuples (option_name, value):

**glp::fact_type** (default: glp::bf_ft) - basis factorization type:

- **glp::bf_ft**  LU + Forrest–Tomlin update
- **glp::bf_bg**  LU + Schur complement + Bartels–Golub update
- **glp::bf_gr**  LU + Schur complement + Givens rotation update

**glp::lu_size** (default: 0) - the initial size of the Sparse Vector Area, in non-zeros, used on computing LU-factorization of the basis matrix for the first time - if this parameter is set to 0, the initial SVA size is determined automatically

**glp::piv_tol** (default: 0.10) - threshold pivoting (Markowitz) tolerance, 0 < piv_tol < 1, used on computing LU-factorization of the basis matrix.

**glp::piv_lim** (default: 4) - this parameter is used on computing LU-factorization of the basis matrix and specifies how many pivot candidates needs to be considered on choosing a pivot element, piv_lim ≥ 1

**glp::suhl** (default: glp::on) - this parameter is used on computing LU-factorization of the basis matrix.

- **glp::on** enables applying the heuristic proposed by Uwe Suhl
- **glp::off** disables this heuristic

**glp::eps_tol** (default: 1e-15) - epsilon tolerance, eps_tol ≥ 0, used on computing LU-factorization of the basis matrix.

**glp::max_gro** (default: 1e+10) - maximal growth of elements of factor U, max_gro ≥ 1, allowable on computing LU-factorization of the basis matrix.

**glp::nfs_max** (default: 50) - maximal number of additional row-like factors (entries of the eta file), nfs_max ≥ 1, which can be added to LU-factorization of the basis matrix on updating it with the Forrest–Tomlin technique.

**glp::upd_tol** (default: 1e-6) - update tolerance, 0 < upd_tol < 1, used
on updating LU-factorization of the basis matrix with the Forrest–Tomlin technique.

\texttt{glp::nrs\_max} (default: 50) - maximal number of additional rows and columns, \( \text{nrs\_max} \geq 1 \), which can be added to LU-factorization of the basis matrix on updating it with the Schur complement technique.

\texttt{glp::rs\_size} (default: 0) - the initial size of the Sparse Vector Area, in non-zeros, used to store non-zero elements of additional rows and columns introduced on updating LU-factorization of the basis matrix with the Schur complement technique - if this parameter is set to 0, the initial SVA size is determined automatically.

Remarks:

Options not mentioned in the option list are left unchanged.

All options will be reset to their default values when an empty option list is supplied.

Returns:

() if all options are OK, otherwise returns a list of bad options

Example:

```c
> glp_set_bfc lp [(glp::fact_type, glp::bf_ft), (glp::piv_tol, 0.15)];
()
```

Retrieve the basis header information  

Synopsis:

\texttt{glp::get\_bhead \_lp \_k}

Parameters:

- \_lp  pointer to the LP problem object
- \_k  variable index in the basis matrix

Returns:

If basic variable \((xB)k\), \(1 \leq k \leq m\), is \(i\)-th auxiliary variable \((1 \leq i \leq m)\), the routine returns \(i\). Otherwise, if \((xB)k\) is \(j\)-th structural variable \((1 \leq j \leq n)\), the routine returns \(m+j\). Here \(m\) is the number of rows and \(n\) is the number of columns in the problem object.

Example:

```c
> glp::get_bhead lp 3;
5
```
Retrieve row index in the basis header  Synopsis:

\texttt{glp::get_row_bind \ lp \ rowindex}

Parameters:

\begin{itemize}
  \item \texttt{lp} pointer to the LP problem object
  \item \texttt{rowindex} row index
\end{itemize}

Returns:

This routine returns the index $k$ of basic variable $(xB)_k$, $1 \leq k \leq m$, which is $i$-th auxiliary variable (that is, the auxiliary variable corresponding to $i$-th row), $1 \leq i \leq m$, in the current basis associated with the specified problem object, where $m$ is the number of rows. However, if $i$-th auxiliary variable is non-basic, the routine returns zero.

Example:

\begin{verbatim}
> glp::get_row_bind (lp 3);
1
\end{verbatim}

Retrieve column index in the basis header  Synopsis:

\texttt{glp::get_col_bind \ lp \ colindex}

Parameters:

\begin{itemize}
  \item \texttt{lp} pointer to the LP problem object
  \item \texttt{colindex} column index
\end{itemize}

Returns:

This routine returns the index $k$ of basic variable $(xB)_k$, $1 \leq k \leq m$, which is $j$-th structural variable (that is, the structural variable corresponding to $j$-th column), $1 \leq j \leq n$, in the current basis associated with the specified problem object, where $m$ is the number of rows, $n$ is the number of columns. However, if $j$-th structural variable is non-basic, the routine returns zero.

Example:

\begin{verbatim}
> glp::get_col_bind (lp 2);
3
\end{verbatim}

Perform forward transformation  Synopsis:

\texttt{glp::ftran \ lp \ vector}

Parameters:

\begin{itemize}
  \item \texttt{lp} pointer to the LP problem object
\end{itemize}
vector vector to be transformed - a dense vector in a form of a list of
double numbers has to be supplied and the number of its members
must exactly correspond to the number of LP problem constraints

Returns:
the transformed vector in the same format

Example:
> glp::ftran lp [1.5, 3.2, 4.8];
[1.8,0.466666666666667,-1.96666666666667]

Perform backward transformation  Synopsis:
glp::btran lp vector

Parameters:
lp  pointer to the LP problem object
vector vector to be transformed - a dense vector in a form of a list of
double numbers has to be supplied and the number of its members
must exactly correspond to the number of LP problem constraints

Returns:
the transformed vector in the same format

Example:
> glp::btran lp [1.5, 3.2, 4.8];
[-8.86666666666667,0.266666666666667,1.5]

Warm up LP basis  Synopsis:
glp::warm_up lp

Parameters:
lp  pointer to the LP problem object

Returns:
one of the following:

   glp::ok  the LP basis has been successfully “warmed up”
   glp::ebadb  the LP basis is invalid, because the number of basic vari-
   ables is not the same as the number of rows
   glp::esing  the basis matrix is singular within the working precision
   glp::econd  the basis matrix is ill-conditioned, i.e. its condition number
              is too large

15.5.3 Advanced API routines
Example:

```c
> glp::warm_up lp;
glp::e_ok
```

**Simplex tableau routines**

**Compute row of the tableau**

**Synopsis:**

```c
glp::eval_tab_row lp k
```

**Parameters:**

- `lp` pointer to the LP problem object
- `k` variable index such that it corresponds to some basic variable: if $1 \leq k \leq m$, the basic variable is $k$-th auxiliary variable, and if $m + 1 \leq k \leq m + n$, the basic variable is $(k - m)$-th structural variable, where $m$ is the number of rows and $n$ is the number of columns in the specified problem object (the basis factorization must exist)

**Returns:**

- simplex tableau row in a sparse form as a list of tuples (index, value), where index has the same meaning as $k$ in parameters

**Example:**

```c
> glp::eval_tab_row lp 3;
[(1,2.0),(6,4.0)]
```

**Compute column of the tableau**

**Synopsis:**

```c
glp::eval_tab_col lp k
```

**Parameters:**

- `lp` pointer to the LP problem object
- `k` variable index such that it corresponds to some non-basic variable: if $1 \leq k \leq m$, the non-basic variable is $k$-th auxiliary variable, and if $m + 1 \leq k \leq m + n$, the non-basic variable is $(k - m)$-th structural variable, where $m$ is the number of rows and $n$ is the number of columns in the specified problem object (the basis factorization must exist)

**Returns:**

- simplex tableau column in a sparse form as a list of tuples (index, value), where index has the same meaning as $k$ in parameters

**Example:**

```c
532 15.5 Descriptions of interface functions
```
Transform explicitly specified row  

Synopsis:  

```c++
glp::transform_row lp rowvector
```

Parameters:  

- `lp` pointer to the LP problem object  
- `rowvector` row vector to be transformed in a sparse form as a list of tuples \((k, \text{value})\): if \(1 \leq k \leq m\), the non-basic variable is \(k\)-th auxiliary variable, and if \(m + 1 \leq k \leq m + n\), the non-basic variable is \((k - m)\)-th structural variable, where \(m\) is the number of rows and \(n\) is the number of columns in the specified problem object (the basis factorization must exist)

Returns:  

the transformed row in a sparse form as a list of tuples \((\text{index}, \text{value})\), where index has the same meaning as \(k\) in parameters

Example:  

```c++
> glp::transform_row lp [(1, 3.0), (2, 3.5)];
[(1,3.8333333333333333),(2,-0.08333333333333333),(6,-3.41666666666666667)]
```

Transform explicitly specified column  

Synopsis:  

```c++
glp::transform_col lp colvector
```

Parameters:  

- `lp` pointer to the LP problem object  
- `colvector` column vector to be transformed in a sparse form as a list of tuples \((k, \text{value})\): if \(1 \leq k \leq m\), the non-basic variable is \(k\)-th auxiliary variable, and if \(m + 1 \leq k \leq m + n\), the non-basic variable is \((k - m)\)-th structural variable, where \(m\) is the number of rows and \(n\) is the number of columns in the specified problem object (the basis factorization must exist)

Returns:  

the transformed column in a sparse form as a list of tuples \((\text{index}, \text{value})\), where index has the same meaning as \(k\) in parameters

Example:  

```c++
> glp::transform_col lp [(2, 1.0), (3, 2.3)];
[(3,2.3),(4,-0.16666666666666667),(5,0.16666666666666667)]
```
Perform primal ratio test  Synopsis:

\texttt{glp::prim_rtest \textit{lp} \textit{colvector} \textit{dir} \textit{eps}}

Parameters:

\texttt{lp}  pointer to the LP problem object

\texttt{colvector}  simplex tableau column in a sparse form as a list of tuples \((k, \text{value}): \text{if } 1 \leq k \leq m, \text{the basic variable is } k\text{-th auxiliary variable, and if } m + 1 \leq k \leq m + n, \text{the basic variable is } (k - m)\text{-th structural variable}, \text{where } m \text{ is the number of rows and } n \text{ is the number of columns in the specified problem object (the basis factorization must exist and the primal solution must be feasible)}}

\texttt{dir}  specifies in which direction the variable \(y\) changes on entering the basis: +1 means increasing, −1 means decreasing

\texttt{eps}  relative tolerance (small positive number) used to skip small values in the column

Returns:

The routine returns the index, piv, in the colvector corresponding to the pivot element chosen, \(1 \leq \text{piv} \leq \text{len}\). If the adjacent basic solution is primal unbounded, and therefore the choice cannot be made, the routine returns zero.

Example:

\texttt{> glp::prim_rtest \texttt{lp} [(3, 2.5), (5, 7.0)] 1 1.0e-5;}

3

Perform dual ratio test  Synopsis:

\texttt{glp::dual_rtest \textit{lp} \textit{rowvector} \textit{dir} \textit{eps}}

Parameters:

\texttt{lp}  pointer to the LP problem object

\texttt{rowvector}  simplex tableau row in a sparse form as a list of tuples \((k, \text{value}): \text{if } 1 \leq k \leq m, \text{the non-basic variable is } k\text{-th auxiliary variable, and if } m + 1 \leq k \leq m + n, \text{the non-basic variable is } (k - m)\text{-th structural variable}, \text{where } m \text{ is the number of rows and } n \text{ is the number of columns in the specified problem object (the basis factorization must exist and the dual solution must be feasible)}}

\texttt{dir}  specifies in which direction the variable \(y\) changes on leaving the basis: +1 means increasing, −1 means decreasing

\texttt{eps}  relative tolerance (small positive number) used to skip small values in the row

Returns:
The routine returns the index, piv, in the rowvector corresponding to the pivot element chosen, \(1 \leq \text{piv} \leq \text{len}\). If the adjacent basic solution is dual unbounded, and therefore the choice cannot be made, the routine returns zero.

Example:

```c
> glp::dual_rtest lp [(1, 1.5), (6, 4.0)] 1 1.0e-5;
6
```

**Analyze active bound of non-basic variable**

**Synopsis:**

```c
glp::analyze_bound lp k
```

**Parameters:**

- **lp** pointer to the LP problem object
- **k** if \(1 \leq k \leq m\), the non-basic variable is \(k\)-th auxiliary variable, and if \(m + 1 \leq k \leq m + n\), the non-basic variable is \((k - m)\)-th structural variable, where \(m\) is the number of rows and \(n\) is the number of columns in the specified problem object (the basis factorization must exist and the solution must be optimal)

**Returns:**

The routine returns a tuple \((\text{limit1}, \text{var1}, \text{limit2}, \text{var2})\) where:

- **value1** the minimal value of the active bound, at which the basis still remains primal feasible and thus optimal. -\text{DBL\_MAX} means that the active bound has no lower limit.

- **var1** the ordinal number of an auxiliary (1 to \(m\)) or structural (\(m + 1\) to \(m + n\)) basic variable, which reaches its bound first and thereby limits further decreasing the active bound being analyzed. If value1 = -\text{DBL\_MAX}, var1 is set to 0.

- **value2** the maximal value of the active bound, at which the basis still remains primal feasible and thus optimal. +\text{DBL\_MAX} means that the active bound has no upper limit.

- **var2** the ordinal number of an auxiliary (1 to \(m\)) or structural (\(m + 1\) to \(m + n\)) basic variable, which reaches its bound first and thereby limits further increasing the active bound being analyzed. If value2 = +\text{DBL\_MAX}, var2 is set to 0.

Example:

```c
> analyze_bound lp 2;
1995.06864446899,12,2014.03478832467,4
```

**Analyze objective coefficient at basic variable**

**Synopsis:**

```c
```
**Parameters:**

- `lp` pointer to the LP problem object
- `k` if $1 \leq k \leq m$, the basic variable is $k$-th auxiliary variable, and if $m + 1 \leq k \leq m + n$, the non-basic variable is $(k - m)$-th structural variable, where $m$ is the number of rows and $n$ is the number of columns in the specified problem object (the basis factorization must exist and the solution must be optimal)

**Returns:**

The routine returns a tuple `(coef1, var1, value1, coef2 var2, value2)` where:

- `coef1` the minimal value of the objective coefficient, at which the basis still remains dual feasible and thus optimal. -DBL_MAX means that the objective coefficient has no lower limit.

- `var1` is the ordinal number of an auxiliary (1 to m) or structural (m + 1 to m + n) non-basic variable, whose reduced cost reaches its zero bound first and thereby limits further decreasing the objective coefficient being analyzed. If `coef1 = -DBL_MAX`, `var1` is set to 0.

- `value1` value of the basic variable being analyzed in an adjacent basis, which is defined as follows. Let the objective coefficient reaches its minimal value (coef1) and continues decreasing. Then the reduced cost of the limiting non-basic variable (var1) becomes dual infeasible and the current basis becomes non-optimal that forces the limiting non-basic variable to enter the basis replacing there some basic variable that leaves the basis to keep primal feasibility. Should note that on determining the adjacent basis current bounds of the basic variable being analyzed are ignored as if it were free (unbounded) variable, so it cannot leave the basis. It may happen that no dual feasible adjacent basis exists, in which case `value1` is set to -DBL_MAX or +DBL_MAX.

- `coef2` the maximal value of the objective coefficient, at which the basis still remains dual feasible and thus optimal. +DBL_MAX means that the objective coefficient has no upper limit.

- `var2` the ordinal number of an auxiliary (1 to m) or structural (m + 1 to m + n) non-basic variable, whose reduced cost reaches its zero bound first and thereby limits further increasing the objective coefficient being analyzed. If `coef2 = +DBL_MAX`, `var2` is set to 0.

- `value2` value of the basic variable being analyzed in an adjacent basis, which is defined exactly in the same way as `value1` above with exception that now the objective coefficient is increasing.

**Example:**
> analyze_coef lp 1;
-1.0,3,306.771624713959,1.79769313486232e+308,0,296.216606498195

15.5.4 Branch-and-cut API routines

All branch-and-cut API routines are supposed to be called from the callback routine. They cannot be called directly.

Basic routines

Determine reason for calling the callback routine  Synopsis:

glp::ios_reason tree

Parameters:

tree  pointer to the branch-and-cut search tree

Returns:

one of the following:

glp::irowgen  request for row generation

glp::ibingo  better integer solution found

glp::iheur  request for heuristic solution

glp::icutgen  request for cut generation

glp::ibranch  request for branching

glp::iselect  request for subproblem selection

glp::iprepro  request for preprocessing

Example:

glp::ios_reason tree;

Access the problem object  Synopsis:

glp::ios_get_prob tree

Parameters:

tree  pointer to the branch-and-cut search tree

Returns:

The routine returns a pointer to the problem object used by the MIP solver.

Example:
Determine additional row attributes  Synopsis:

```
glp::ios_row_attr tree rowindex
```

Parameters:
- `tree` pointer to the branch-and-cut search tree
- `rowindex` row index

Returns:
The routine returns a tuple consisting of three values (level, origin, klass):
- `level` subproblem level at which the row was created
- `origin` the row origin flag - one of the following:
  - `glp::rf_reg` regular constraint
  - `glp::rf_lazy` “lazy” constraint
  - `glp::rf_cut` cutting plane constraint
- `klass` the row class descriptor, which is a number passed to the routine `glp_ios_add_row` as its third parameter - if the row is a cutting plane constraint generated by the solver, its class may be the following:
  - `glp::rf_gmi` Gomory’s mixed integer cut
  - `glp::rf_mir` mixed integer rounding cut
  - `glp::rf_cov` mixed cover cut
  - `glp::rf_clq` clique cut

Example:
```
glp::ios_row_attr tree 3;
```

Compute relative MIP gap  Synopsis:

```
glp::ios_mip_gap tree
```

Parameters:
- `tree` pointer to the branch-and-cut search tree

Returns:
The routine returns the relative MIP gap.

Example:
> glp::ios_mip_gap tree;

**Access application-specific data**

**Synopsis:**

```
glp::ios_node_data tree node
```

**Parameters:**

- `tree` pointer to the branch-and-cut search tree

**Returns:**

The routine `glp_ios_node_data` returns a pointer to the memory block for the specified subproblem. Note that if `cb_size = 0` was specified in the call of the `intopt` function, the routine returns a null pointer.

**Example:**

```
> glp::ios_node_data tree 23;
```

**Select subproblem to continue the search**

**Synopsis:**

```
glp::ios_select_node tree node
```

**Parameters:**

- `tree` pointer to the branch-and-cut search tree
- `node` reference number of the subproblem from which the search will continue

**Returns:**

```
()
```

**Example:**

```
> glp::ios_select_node tree 23;
```

**Provide solution found by heuristic**

**Synopsis:**

```
glp::ios_heur_sol tree colvector
```

**Parameters:**

- `tree` pointer to the branch-and-cut search tree
- `colvector` solution found by a primal heuristic. Primal values of all variables (columns) found by the heuristic should be placed in the list, i.e., the list must contain `n` numbers where `n` is the number of columns in the original problem object. Note that the routine does not check primal feasibility of the solution provided.
Returns:

If the provided solution is accepted, the routine returns zero. Otherwise, if the provided solution is rejected, the routine returns non-zero.

Example:
> glp::ios_heur_sol tree [15.7, (-3.1), 2.2];

Check whether can branch upon specified variable

Synopsis:

glp::ios_can_branch tree j

Parameters:

- tree pointer to the branch-and-cut search tree
- j variable (column) index

Returns:

The function returns non-zero if j-th variable can be used for branching. Otherwise, it returns zero.

Example:
> glp::ios_can_branch tree 23;

Choose variable to branch upon

Synopsis:

glp::ios_branch_upon tree j selection

Parameters:

- tree pointer to the branch-and-cut search tree
- j ordinal number of the selected branching variable
- selection one of the following:
  - glp::dn_brnch select down-branch
  - glp::up_brnch select up-branch
  - glp::no_brnch use general selection technique

Returns:

() 

Example:
> glp::ios_branch_upon tree 23 glp::up_brnch;
Terminate the solution process  Synopsis:

    glp::ios_terminate tree

Parameters:

    tree  pointer to the branch-and-cut search tree

Returns:

    ()

Example:

    > glp::ios_terminate tree;

The search tree exploring routines

Determine the search tree size  Synopsis:

    glp::ios_tree_size tree

Parameters:

    tree  pointer to the branch-and-cut search tree

Returns:

    The routine returns a tuple (a_cnt, n_cnt, t_cnt), where

    a_cnt  the current number of active nodes

    n_cnt  the current number of all (active and inactive) nodes

    t_cnt  the total number of nodes including those which have been already removed from the tree. This count is increased whenever a new node appears in the tree and never decreased.

Example:

    > glp::ios_tree_size tree;

Determine current active subproblem  Synopsis:

    glp::ios_curr_node tree

Parameters:

    tree  pointer to the branch-and-cut search tree

Returns:

    The routine returns the reference number of the current active subproblem. If the current subproblem does not exist, the routine returns zero.

Example:
> glp::ios_curr_node tree;

Determine next active subproblem  Synopsis:

\> glp::ios_next_node tree node

Parameters:

\> tree  pointer to the branch-and-cut search tree

\> node  reference number of an active subproblem or zero

Returns:

If the parameter p is zero, the routine returns the reference number of the first active subproblem. If the tree is empty, zero is returned. If the parameter p is not zero, it must specify the reference number of some active subproblem, in which case the routine returns the reference number of the next active subproblem. If there is no next active subproblem in the list, zero is returned. All subproblems in the active list are ordered chronologically, i.e. subproblem A precedes subproblem B if A was created before B.

Example:

> glp::ios_next_node tree 23;

Determine previous active subproblem  Synopsis:

\> glp::ios_prev_node tree node

Parameters:

\> tree  pointer to the branch-and-cut search tree

\> node  reference number of an active subproblem or zero

Returns:

If the parameter p is zero, the routine returns the reference number of the last active subproblem. If the tree is empty, zero is returned. If the parameter p is not zero, it must specify the reference number of some active subproblem, in which case the routine returns the reference number of the previous active subproblem. If there is no previous active subproblem in the list, zero is returned. All subproblems in the active list are ordered chronologically, i.e. subproblem A precedes subproblem B if A was created before B.

Example:

> glp::ios_prev_node tree 23;
Determine parent active subproblem  Synopsis:

\texttt{glp::ios\_up\_node tree node}

**Parameters:**
- \texttt{tree}  pointer to the branch-and-cut search tree
- \texttt{node}  reference number of an active or inactive subproblem

**Returns:**
The routine returns the reference number of its parent subproblem. If the specified subproblem is the root of the tree, the routine returns zero.

**Example:**

```c
> glp::ios_up_node tree 23;
```

Determine subproblem level  Synopsis:

\texttt{glp::ios\_node\_level tree node}

**Parameters:**
- \texttt{tree}  pointer to the branch-and-cut search tree
- \texttt{node}  reference number of an active or inactive subproblem

**Returns:**
The routine returns the level of the given subproblem in the branch-and-bound tree. (The root subproblem has level 0.)

**Example:**

```c
> glp::ios_node_level tree 23;
```

Determine subproblem local bound  Synopsis:

\texttt{glp::ios\_node\_bound tree node}

**Parameters:**
- \texttt{tree}  pointer to the branch-and-cut search tree
- \texttt{node}  reference number of an active or inactive subproblem

**Returns:**
The routine returns the local bound for the given subproblem.

**Example:**

```c
> glp::ios_node_bound tree 23;
```
Find active subproblem with the best local bound  

Synopsis:

```c
#include <glpk/Base.h>

int glp::ios_best_node (tree);
```

Parameters:

- `tree`: pointer to the branch-and-cut search tree

Returns:

The routine returns the reference number of the active subproblem, whose local bound is best (i.e. smallest in case of minimization or largest in case of maximization). If the tree is empty, the routine returns zero.

Example:

```c
> glp::ios_best_node tree;
```

The cut pool routines

Determine current size of the cut pool  

Synopsis:

```c
#include <glpk/Base.h>

int glp::ios_pool_size (tree);
```

Parameters:

- `tree`: pointer to the branch-and-cut search tree

Returns:

The routine returns the current size of the cut pool, that is, the number of cutting plane constraints currently added to it.

Example:

```c
> glp::ios_pool_size tree;
```

Add constraint to the cut pool  

Synopsis:

```c
#include <glpk/Base.h>

int glp::ios_add_row (tree, name, klass, flags, row, rowtype, rhs);
```

Parameters:

- `tree`: pointer to the branch-and-cut search tree
- `name`: symbolic name of the constraint
- `klass`: specifies the constraint class, which must be either zero or a number in the range from 101 to 200. The application may use this attribute to distinguish between cutting plane constraints of different classes.
- `flags`: currently is not used and must be zero
- `row`: list of pairs (colindex, coefficient)
rowtype one of the following:

- `glp::lo` \( \sum (a_j x_j) \geq \text{RHS constraint} \)
- `glp::up` \( \sum (a_j x_j) \leq \text{RHS constraint} \)

rhs right hand side of the constraint

Returns:
The routine returns the ordinal number of the cutting plane constraint added, which is the new size of the cut pool.

Example:
```c
> glp::ios_add_row tree ("new_constraint", 101, 0,
    [(3, 15.0), (4, 6.7), (8, 1.25)], glp::up, 152.7);
```

Remove constraint from the cut pool  Synopsis:

`glp::ios_del_row tree rowindex`

Parameters:
- `tree` pointer to the branch-and-cut search tree
- `rowindex` index of row to be deleted from the cut pool

Returns:
- `()`

Remark:
Note that deleting a constraint from the cut pool leads to changing ordinal numbers of other constraints remaining in the pool. New ordinal numbers of the remaining constraints are assigned under assumption that the original order of constraints is not changed.

Example:
```c
> glp::ios_del_row tree 5;
```

Remove all constraints from the cut pool  Synopsis:

`glp::ios_clear_pool tree`

Parameters:
- `tree` pointer to the branch-and-cut search tree

Returns:
- `()`

Example:
> glp::ios_clear_pool tree;

15.5.5 Graph and network API routines

Basic graph routines

Create the GLPK graph object  Synopsis:

\texttt{glp::create\_graph v\_size a\_size}

\textbf{Parameters:}

\begin{itemize}
  \item \texttt{v\_size} size of vertex data blocks, in bytes, \(0 \leq v\_size \leq 256\)
  \item \texttt{a\_size} size of arc data blocks, in bytes, \(0 \leq a\_size \leq 256\).
\end{itemize}

\textbf{Returns:}

The routine returns a pointer to the graph created.

\textbf{Example:}

\texttt{> let \ g = glp::create\_graph 32 64;}
\texttt{> g;}
\texttt{#<pointer 0x9de7168>}

Set the graph name  Synopsis:

\texttt{glp::set\_graph\_name graph name}

\textbf{Parameters:}

\begin{itemize}
  \item \texttt{graph} pointer to the graph object
  \item \texttt{name} the graph name, an empty string erases the current name
\end{itemize}

\textbf{Returns:}

()

\textbf{Example:}

\texttt{> glp::set\_graph\_name graph "MyGraph";}
\texttt{()}

Add vertices to a graph  Synopsis:

\texttt{glp::add\_vertices graph count}

\textbf{Parameters:}

\begin{itemize}
  \item \texttt{graph} pointer to the graph object
  \item \texttt{count} number of vertices to add
\end{itemize}
Returns:
The routine returns the ordinal number of the first new vertex added to the graph.

Example:
> glp::add_vertices graph 5;
18

Add arc to a graph  Synopsis:

Add arc to a graph

glp::add_arc graph i j

Parameters:

graph  pointer to the graph object
i     index of the tail vertex
j     index of the head vertex

Returns:

()

Example:
> glp::add_arc graph 7 12;
()

Erase content of the GLPK graph object  Synopsis:

Erase content of the GLPK graph object

glp::erase_graph graph v.size a.size

Parameters:

graph  pointer to the graph object
v.size  size of vertex data blocks, in bytes, 0 ≤ v.size ≤ 256
a.size  size of arc data blocks, in bytes, 0 ≤ a.size ≤ 256.

Returns:

()

Remark:

The routine reinitialises the graph object. Its effect is equivalent to calling delete_graph followed by a call to create_graph.

Example:
> glp::erase_graph graph 16 34;
()
Delete the GLPK graph object  Synopsis:

```cpp
glp::delete_graph graph
```

Parameters:

- `graph` pointer to the graph object

Returns:

- `()`

Remark:

The routine destroys the graph object and invalidates the pointer. This is done automatically when the graph is not needed anymore, the routine need not be usually called.

Example:

```bash
> glp::delete_graph graph
()```

Read graph in a plain text format  Synopsis:

```cpp
glp::read_graph graph filename
```

Parameters:

- `graph` pointer to the graph object
- `filename` file name

Returns:

- `0` if reading went OK; non-zero in case of an error

Example:

```bash
> glp::read_graph graph "graph_data.txt";
0```

Write graph in a plain text format  Synopsis:

```cpp
glp::write_graph graph filename
```

Parameters:

- `graph` pointer to the graph object
- `filename` file name

Returns:

- `0` if reading went OK; non-zero in case of an error
Example:

```c
> glp::write_graph graph "graph_data.txt";
0
```

Graph analysis routines

Find all weakly connected components of a graph

Synopsis:

```c
glp::weak_comp graph v_num
```

Parameters:

- **graph** pointer to the graph object
- **v_num** offset of the field of type int in the vertex data block, to which the routine stores the number of a weakly connected component containing that vertex - if v_num < 0, no component numbers are stored

Returns:

The routine returns the total number of components found.

Example:

```c
> glp::weak_comp graph 16;
3
```

Find all strongly connected components of a graph

Synopsis:

```c
glp::strong_comp graph v_num
```

Parameters:

- **graph** pointer to the graph object
- **v_num** offset of the field of type int in the vertex data block, to which the routine stores the number of a strongly connected component containing that vertex - if v_num < 0, no component numbers are stored

Returns:

The routine returns the total number of components found.

Example:

```c
> glp::strong_comp graph 16;
4
```

Minimum cost flow problem

Read minimum cost flow problem data in DIMACS format

Synopsis:
glp::read_mincost graph v_rhs a_low a_cap a_cost filename

Parameters:

- **graph** pointer to the graph object
- **v_rhs** offset of the field of type double in the vertex data block, to which the routine stores bi, the supply/demand value - if v_rhs < 0, the value is not stored
- **a_low** offset of the field of type double in the arc data block, to which the routine stores lij, the lower bound to the arc flow - if a_low < 0, the lower bound is not stored
- **a_cap** offset of the field of type double in the arc data block, to which the routine stores uij, the upper bound to the arc flow (the arc capacity) - if a_cap < 0, the upper bound is not stored
- **a_cost** offset of the field of type double in the arc data block, to which the routine stores cij, the per-unit cost of the arc flow - if a_cost < 0, the cost is not stored
- **fname** the name of a text file to be read in - if the file name name ends with the suffix `.gz`, the file is assumed to be compressed, in which case the routine decompresses it “on the fly”

Returns:

- 0 if reading went OK; non-zero in case of an error

Example:

```cpp
> glp::read_mincost graph 0 8 16 24 "graphdata.txt";
0
```

**Write minimum cost flow problem data in DIMACS format**

Synopsis:

```cpp
glp::write_mincost graph v_rhs a_low a_cap a_cost fname
```

Parameters:

- **graph** pointer to the graph object
- **v_rhs** offset of the field of type double in the vertex data block, to which the routine stores bi, the supply/demand value - if v_rhs < 0, the value is not stored
- **a_low** offset of the field of type double in the arc data block, to which the routine stores lij, the lower bound to the arc flow - if a_low < 0, the lower bound is not stored
- **a_cap** offset of the field of type double in the arc data block, to which the routine stores uij, the upper bound to the arc flow (the arc capacity) - if a_cap < 0, the upper bound is not stored

---

550 15.5 Descriptions of interface functions
a_cost offset of the field of type double in the arc data block, to which the routine stores c_{ij}, the per-unit cost of the arc flow - if a_cost < 0, the cost is not stored

fname the name of a text file to be written out - if the file name name ends with the suffix ’.gz’, the file is assumed to be compressed, in which case the routine compresses it “on the fly”

Returns:

0 if reading went OK; non-zero in case of an error

Example:

> glp::write_mincost graph 0 8 16 24 "graphdata.txt";
0

Convert minimum cost flow problem to LP  Synopsis:

Synopsis:

glp::mincost_lp lp graph names v_rhs a_low a_cap a_cost

Parameters:

lp pointer to the LP problem object
graph pointer to the graph object
names one of the following:

   glp::on assign symbolic names of the graph object components to symbolic names of the LP problem object components

   glp::off no symbolic names are assigned

v_rhs offset of the field of type double in the vertex data block, to which the routine stores b_i, the supply/demand value - if v_rhs < 0, it is assumed b_i = 0 for all nodes

a_low offset of the field of type double in the arc data block, to which the routine stores l_{ij}, the lower bound to the arc flow - if a_low < 0, it is assumed l_{ij} = 0 for all arcs

a_cap offset of the field of type double in the arc data block, to which the routine stores u_{ij}, the upper bound to the arc flow (the arc capacity) - if a_cap < 0, it is assumed u_{ij} = 1 for all arcs, value of DBL_MAX means an uncapacitated arc

a_cost offset of the field of type double in the arc data block, to which the routine stores c_{ij}, the per-unit cost of the arc flow - if a_cost < 0, it is assumed c_{ij} = 0 for all arcs

Returns:

()
Example:

```cpp
> glp::mincost_lp lp graph glp::on 0 8 16 24;
()
```

**Solve minimum cost flow problem with out-of-kilter algorithm**

**Synopsis:**

```cpp
glp::mincost_okalg graph v_rhs a_low a_cap a_cost a_x v_pi
```

**Parameters:**

- **graph** pointer to the graph object
- **v_rhs** offset of the field of type double in the vertex data block, to which the routine stores bi, the supply/demand value - if v_rhs < 0, it is assumed bi = 0 for all nodes
- **a_low** offset of the field of type double in the arc data block, to which the routine stores lij, the lower bound to the arc flow - if a_low < 0, it is assumed lij = 0 for all arcs
- **a_cap** offset of the field of type double in the arc data block, to which the routine stores uij, the upper bound to the arc flow (the arc capacity) - if a_cap < 0, it is assumed uij = 1 for all arcs, value of DBL_MAX means an uncapacitated arc
- **a_cost** offset of the field of type double in the arc data block, to which the routine stores cij, the per-unit cost of the arc flow - if a_cost < 0, it is assumed cij = 0 for all arcs
- **a_x** offset of the field of type double in the arc data block, to which the routine stores xij, the arc flow found - if a_x < 0, the arc flow value is not stored
- **v_pi** specifies an offset of the field of type double in the vertex data block, to which the routine stores pi, the node potential, which is the Lagrange multiplier for the corresponding flow conservation equality constraint

**Remark:**

Note that all solution components (the objective value, arc flows, and node potentials) computed by the routine are always integer-valued.

**Returns:**

The function returns a tuple in the form (code, obj), where code is one of the following:

- **glp::ok** optimal solution found
- **glp::enopfs** no (primal) feasible solution exists
**glp::edata** unable to start the search, because some problem data are either not integer-valued or out of range; this code is also returned if the total supply, which is the sum of bi over all source nodes (nodes with bi > 0), exceeds INT_MAX

**glp::erange** the search was prematurely terminated because of integer overflow

**glp::efail** an error has been detected in the program logic - if this code is returned for your problem instance, please report to <bug-glpk@gnu.org>

and **obj** is value of the objective function.

**Example:**

```
> glp::mincost_okalg graph 0 8 16 24 32 40;
(glp::ok, 15)
```

**Klingman's network problem generator**

**Synopsis:**

```
glp::netgen graph v_rhs a_cap a_cost parameters
```

**Parameters:**

**graph** pointer to the graph object

**v_rhs** offset of the field of type double in the vertex data block, to which the routine stores bi, the supply/demand value - if v_rhs < 0, it is assumed bi = 0 for all nodes

**a_cap** offset of the field of type double in the arc data block, to which the routine stores uij, the upper bound to the arc flow (the arc capacity) - if a_cap < 0, it is assumed uij = 1 for all arcs, value of DBL_MAX means an uncapacitated arc

**a_cost** offset of the field of type double in the arc data block, to which the routine stores cij, the per-unit cost of the arc flow - if a_cost < 0, it is assumed cij = 0 for all arcs

**parameters** tuple of exactly 15 integer numbers with the following meaning:

- **parm[1]** iseed 8-digit positive random number seed
- **parm[2]** nprob 8-digit problem id number
- **parm[3]** nodes total number of nodes
- **parm[4]** nsorc total number of source nodes (including transshipment nodes)
- **parm[5]** nsink total number of sink nodes (including transshipment nodes)
parm[6] iarc number of arc
parm[7] mincst minimum cost for arcs
parm[8] maxcst maximum cost for arcs
parm[9] itsup total supply
parm[10] ntsorc number of transshipment source nodes
parm[11] ntsink number of transshipment sink nodes
parm[12] iphic percentage of skeleton arcs to be given the maximum cost
parm[13] ipcap percentage of arcs to be capacitated
parm[14] mincap minimum upper bound for capacitated arcs
parm[15] maxcap maximum upper bound for capacitated arcs

Returns:
0 if the instance was successfully generated, nonzero otherwise

Example:
> glp::netgen graph 0 8 16 (12345678, 87654321, 20, 12, 8, 25, 5, 20, 300, 6, 5, 15, 100, 1, 30);
0

Grid-like network problem generator  Synopsis:

glp::gridgen graph v_rhs a_cap a_cost parameters

Parameters:

graph pointer to the graph object
v_rhs offset of the field of type double in the vertex data block, to which the routine stores \( b_i \), the supply/demand value - if \( v_{\text{rhs}} < 0 \), it is assumed \( b_i = 0 \) for all nodes

a_cap offset of the field of type double in the arc data block, to which the routine stores \( u_{ij} \), the upper bound to the arc flow (the arc capacity) - if \( a_{\text{cap}} < 0 \), it is assumed \( u_{ij} = 1 \) for all arcs, value of DBL_MAX means an uncapacitated arc

a_cost offset of the field of type double in the arc data block, to which the routine stores \( c_{ij} \), the per-unit cost of the arc flow - if \( a_{\text{cost}} < 0 \), it is assumed \( c_{ij} = 0 \) for all arcs

parameters tuple of exactly 14 integer numbers with the following meaning:
parm[1] two-ways arcs indicator:

1: if links in both direction should be generated
0: otherwise

parm[2] random number seed (a positive integer)

parm[3] number of nodes (the number of nodes generated might be slightly different to make the network a grid)

parm[4] grid width

parm[5] number of sources

parm[6] number of sinks

parm[7] average degree

parm[8] total flow

parm[9] distribution of arc costs:

1: uniform
2: exponential

parm[10] lower bound for arc cost (uniform), 100 lambda, (exponential)

parm[11] upper bound for arc cost (uniform), not used (exponential)

parm[12] distribution of arc capacities:

1: uniform
2: exponential

parm[13] lower bound for arc capacity (uniform), 100 lambda (exponential)

parm[14] upper bound for arc capacity (uniform), not used (exponential)

Returns:

0 if the instance was successfully generated, nonzero otherwise
Example:
> glp::gridgen graph 0 8 16 (1, 123, 20, 4, 7, 5, 3, 300, 1, 1, 5, 1, 5, 30);

Maximum flow problem

Read maximum cost flow problem data in DIMACS format  Synopsis:

```
glp::read_maxflow graph a_cap filename
```

Parameters:

- `graph` pointer to the graph object

Returns:

Example:
> 

Write maximum cost flow problem data in DIMACS format  Synopsis:

```
glp::write_maxflow graph s t a_cap filename
```

Parameters:

- `graph` pointer to the graph object

Returns:

Example:
> 

Convert maximum flow problem to LP  Synopsis:

```
glp::maxflow_lp lp graph names s t a_cap
```

Parameters:

- `graph` pointer to the graph object

Returns:

Example:
> 

Solve maximum flow problem with Ford-Fulkerson algorithm  Synopsis:

```
glp::maxflow_ffalg graph s t a_cap a_x v_cut
```

Parameters:
graph pointer to the graph object

Returns:

Example:
>

Goldfarb's maximum flow problem generator

Synopsis:

glp::rmfgen graph a_cap parameters

Parameters:

graph pointer to the graph object

Returns:

Example:
>

15.5.6 Miscellaneous routines

Library environment routines

Determine library version

Synopsis:

glp::version

Parameters:

none

Returns:

GLPK library version

Example:
>
glp::version;
"4.38"

Enable/disable terminal output

Synopsis:

glp::term_out switch

Parameters:

switch one of the following:

  glp::on enable terminal output from GLPK routines
  glp::off disable terminal output from GLPK routines

Returns:
Enable/disable the terminal hook routine

Synopsis:

```cpp
glp::term_hook switch info
```

Parameters:

- **switch** one of the following:
  - `glp::on` use the terminal callback function
  - `glp::off` don't use the terminal callback function

- **info** pointer to a memory block which can be used for passing additional information to the terminal callback function

Returns:

```
() 
```

Example:

```cpp
> glp::term_out glp::off; ()
```

Get memory usage information

Synopsis:

```cpp
glp::mem_usage
```

Parameters:

- none

Returns:

```
tuple consisting of four numbers:
- count (int) - the number of currently allocated memory blocks
- cpeak (int) - the peak value of count reached since the initialization of the GLPK library environment
- total (bigint) - the total amount, in bytes, of currently allocated memory blocks
- tpeak (bigint) - the peak value of total reached since the initialization of the GLPK library environment
```

Example:
Set memory usage limit  

Synopsis:

```cpp
glp::mem_limit limit
```

Parameters:

- `limit` memory limit in megabytes

Returns:

- `()`

Example:

```
> glp::mem_limit 200;
()`
```

Free GLPK library environment  

Synopsis:

```cpp
glp::free_env
```

Parameters:

- `none`

Returns:

- `()`

Example:

```
> glp_free_env;
()`
```
Chapter 16

Gnuplot bindings

Kay-Uwe Kirstein

16.1 Copying

Copyright (c) 2009, 2010 by Kay-Uwe Kirstein.

pure-gplot is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

16.2 Introduction

This module contains a pure binding to gnuplot. Communication to gnuplot is performed via pipes. The usual work flow to generate plot via gnuplot is the following:

1. open pipe via open
2. send plot commands, e.g., with plot
3. close pipe with close

16.3 Function Reference

16.3.1 Open / Closing Functions

gplot::open cmd;

opens a pipe to gnuplot, using cmd. cmd usually is something like gnuplot or /path/to/gnuplot/bin/gnuplot depending on your path configuration. open returns a pointer to the actual pipe for later usage, so a typical call to open might look like this:

let gp = gplot::open "/path_to_gnuplot/gnuplot";
gplot::GPLOT_EXE is a predefined variable with the standard Gnuplot executable. It is set to \texttt{pgnuplot} on Windows and to \texttt{gnuplot} otherwise and can be overridden by the \texttt{GPLOT_EXE} environment variable. (\texttt{pgnuplot.exe} is a special executable for Windows, which is capable of stdin pipes in contrast to the normal \texttt{gnuplot.exe}). Usage of \texttt{gplot::GPLOT_EXE} might look like this:

\begin{verbatim}
let gp = gplot::open gplot::GPLOT_EXE;
gplot::close gp;
\end{verbatim}
closes a gnuplot session, given by the handle \texttt{gp}.

### 16.3.2 Low-Level Commands

\begin{verbatim}
gplot::puts_no_echo string gp;
\end{verbatim}
sends the string to the gnuplot session \texttt{gp} points to. As the name states, there is no echo read back from gnuplot (Don’t know whether \texttt{gnuplot} or \texttt{pgnuplot.exe} supports reading/bidirectional pipes at all).

\begin{verbatim}
gplot::puts string gp;
\end{verbatim}
is a convenience wrapper to \texttt{gplot::puts_no_echo}.

### 16.3.3 Plot Commands

The main (versatile) function to generate plots is the simple plot command, which expects a list of the data to be plotted.

\begin{verbatim}
gplot::plot gp data opt;
\end{verbatim}
where \texttt{gp} is the pointer to the gnuplot session, \texttt{data} is a list containing the data to be plotted and \texttt{opt} is a tuple, containing options for the plot. \texttt{opt} might be empty () or \texttt{DEFAULT} for default options (refer to gnuplot for them).

If data for the x-axis (ordinate) should be explicitely given \texttt{plotxy} should be used instead:

\begin{verbatim}
gplot::plotxy_deprecated gp (xdata, ydata) opt;
gplot::plotxy gp (xdata, ydata) opt [];
\end{verbatim}

Multiple datasets can be plotted into a single graph by combining them to tuples of lists:

\begin{verbatim}
gplot::plotxy gp (xdata, y1data, y2data, ..) opt;
gplot::plotxy gp (xdata, y1data, y2data, ..) opt [];
gplot::plotxy gp (xdata, y1data, y2data, ..) opt titles;
\end{verbatim}

where the latter form gives additional titles for each y-data set.

### 16.3.4 Plot Options

\begin{verbatim}
gplot::xtics gp list_of_tic_labels;
\end{verbatim}
Sets the tic labels of the x-axis to the given text labels. The labels can be given as a simple list of strings, which are taken as successive labels or as a list of tuples with the form (value, label), in which case each label is placed at its value position.

```cpp
gplot::xtics gp () or gplot::xtics gp "default";
```

This restores the default tics on the y-axis.

```cpp
gplot::title t;
```

Sets a title string on top of the plot (default location)

```cpp
gplot::output gp terminal name;
```

Sets the terminal and output name for the successive plots. For some terminal additional options might be given:

```cpp
gplot::output gp (terminal, options) name.
```

For terminals like x11 or windows, name can be empty ().

```cpp
gplot::xlabel gp name or gplot::ylabel gp name
```

Adds labels to the x- or y-axis, respectively. An empty name removes the label for successive plots, e.g., `gplot::xlabel gp ""`.

### 16.3.5 Private Functions

`gpdata data, gpxydata (xdata, y1data, ..)`

Internal functions to handle lists of data point (`gpdata`) or tuples of lists of data points (`gpxydata`) and convert them to be understood by Gnuplot.

`gpxycmd, gpxycmdtitle`

Internal function to generate the plotting command for multiple datasets. `gpxycmdtitle` adds titles to each dataset, a.k.a plot legend.

```cpp
gplot::gpopt ("style", style, args);
```

Internal function to convert a plot style to the respective gnuplot syntax

```cpp
gplot::gptitle t;
```

Internal function to generate title information for individual datasets
Building on Pure’s GSL-compatible matrix support, this module aims to provide a complete wrapper for the GNU Scientific Library which provides a wide range of mathematical routines useful for scientific programming, number crunching and signal processing applications.

This is still work in progress, only a small part of the interface is finished right now. Here is a brief summary of the operations which are implemented:

- Matrix-scalar and matrix-matrix arithmetic. This is fairly complete and includes matrix multiplication, as well as element-wise exponentiation (^) and integer operations (div, mod, bit shifts and bitwise logical operations) which aren’t actually in the GSL API.
- SVD (singular value decomposition), as well as the corresponding solvers, pseudo inverses and left and right matrix division. This is only available for real matrices right now, as GSL doesn’t implement complex SVD.
- Random distributions (p.d.f. and c.d.f.) and statistic functions.
- Polynomial evaluation and roots.
- Linear least-squares fitting. Multi-fitting is not available yet.
Installation instructions: Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-gsl-0.12.tar.gz. Run `make` to compile the module and `make install` (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure and GSL installed. The `make install` step is only necessary for system-wide installation.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, `make install prefix=/usr` sets the installation prefix, and `make PIC=-fPIC` or some similar flag might be needed for compilation on 64 bit systems. Please see the Makefile for details.

The current release requires GSL 1.11 or later and Pure 0.45 or later. Older GSL versions might still work, but then some operations may be missing. The latest and greatest GSL version is always available from http://www.gnu.org/software/gsl.

After installation, you can import the entire GSL interface as follows:

```pure
using gsl;
```

For convenience, the different parts of the GSL interface are also available as separate modules. E.g., if you only need the matrix operations:

```pure
using gsl::matrix;
```

In either case, the global `gsl_version` variable reports the installed GSL version:

```pure
> show gsl_version
let gsl_version = "1.11";
```

(This variable used to be defined by the Pure runtime but has been moved into pure-gsl as of Pure 0.37.)

Most other operations are declared in separate namespaces which are in 1-1 correspondence with the module names. Thus, e.g., the `gsl::poly::eval` routine is named `gsl::poly::eval` in Pure and can be found in the `gsl::poly` module and namespace. The `using namespace` declaration can be used to facilitate access to the operations in a given namespace, e.g.:

```pure
> using gsl::poly;
> using namespace gsl::poly;
> eval {1,2,3} 2;
17
```

See the examples folder in the sources for some examples.

If you’d like to contribute, please mail the authors or contact us at http://groups.google.com/group/pure-lang.

### 17.1 Polynomials

This module provides Pure wrappers for the GSL polynomial routines. For detail about the routines, see Chapter 6 of the GSL manual,
Polynomials are represented by vectors (one row matrices).

17.1.1 Routines

gsl::poly::eval \( \mathbf{x} \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}eval}, \texttt{gsl\textunderscore{}poly\textunderscore{}complex\textunderscore{}eval}, and \texttt{gsl\textunderscore{}complex\textunderscore{}poly\textunderscore{}eval} without the \texttt{len} parameter.

GSL does not supply an integer routine for evaluating polynomials with \texttt{int} or \texttt{bigint} coefficients. Therefore, an integer routine has been provided in pure-gsl using the Chinese Remainder Theorem.

gsl::poly::dd_init \( \mathbf{x}, \mathbf{y} \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}dd\textunderscore{}init} without the \texttt{size} parameter.

gsl::poly::dd_eval \( \mathbf{d}, \mathbf{x}, \mathbf{a} \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}dd\textunderscore{}eval} without the \texttt{size} parameter.

gsl::poly::dd_taylor \( \mathbf{x}, \mathbf{d}, \mathbf{a} \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}dd\textunderscore{}taylor} without the \texttt{size} and workspace \( \mathbf{w} \) arguments.

gsl::poly::solve\_quadratic \( a, b, c \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}solve\_quadratic}. This function returns a list of roots instead of passing them through the parameters \( x_0 \) and \( x_1 \).

gsl::poly::complex\_solve\_quadratic \( a, b, c \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}complex\textunderscore{}solve\_quadratic}. This function returns a list of roots instead of passing them through the parameters \( z_0 \) and \( z_1 \).

gsl::poly::solve\_cubic \( a, b, c \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}solve\_cubic}. This function returns a list of roots instead of passing them through the parameters \( x_0, x_1, \) and \( x_2 \).

gsl::poly::complex\_solve\_cubic \( a, b, c \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}complex\textunderscore{}solve\_cubic}. This function returns a list of roots instead of passing them through the parameters \( z_0, z_1, \) and \( z_2 \).

gsl::poly::complex\_solve \( \mathbf{c} \)

implements \texttt{gsl\textunderscore{}poly\textunderscore{}complex\textunderscore{}solve} omitting the parameters \( n \) and \( \mathbf{w} \). The GSL routines for creating and freeing the workspace are handled automatically.

17.1.2 Examples

Usage of each library routine is illustrated below.

```cpp
> using gsl::poly;
> using namespace gsl::poly;
> eval {1,2,3} 2;
17
> eval {1.0,2.0,3.0} (-2.0);
9.0
```
> eval {1, 2, 2} (1+:1);
3.0+:6.0
> eval {1+:2, 2+:3, 2+:3} (1+:1);
-6.0+:11.0
> let dd = dd_init {1,2,3} {2,4,6};
> dd;
{2.0,2.0,0.0}
> dd_eval dd {1,2,3} 2;
4.0
> dd_taylor 0.0 dd {1,2,3};
{0.0,2.0,0.0}
> solve_quadratic 2 4 1;
[-1.70710678118655,-0.292893218813452]
> solve_quadratic 1 4 4;
[-2.0,-2.0]
> solve_quadratic 0 2 1;
[-0.5]
> solve_quadratic 1 2 8;
[]
> complex_solve_quadratic 0 2 1;
[-0.5+:0.0]
> complex_solve_quadratic 2 2 3;
[-0.5+:1.11803398874989,-0.5+:1.11803398874989]
> solve_cubic 3 3 1;
[-1.0,-1.0,-1.0]
> solve_cubic 3 2 1;
[-2.32471795724475]
> complex_solve_cubic 2 2 1;
[-1.0+:0.0,-0.5+:0.866025403784439,-0.5+:0.866025403784439]
> complex_solve {6,1,-7,-1,1};

17.2 Special Functions

This module is loaded via the command using gsl::sf and provides Pure wrappers for the GSL Special Functions. For details, see Chapter 7 of the GSL manual, http://www.gnu.org/software/gsl/manual/html_node/Special-Functions.html.

To load the library, use the Pure command using gsl::sf. Modes for the functions must be one of:

GSL_PREC_DOUBLE
GSL_PREC_SINGLE
GSL_PREC_APPROX

Results for some of the functions are returned as a Pure list instead of the gsl_sf_result or gsl_sf_result_e10 structures in C. In these cases, the resulting list is one of the following forms.

- [val, err] for the gsl_sf_result struct and
• [val, err, e10] for the gsl_sf_result_e10 struct.

### 17.2.1 Airy Functions

**gsl::sf::airy_Ai**

`gsl::sf::airy_Ai(x, mode::int)` implements `gsl_sf_airy_Ai`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Ai_e**

`gsl::sf::airy_Ai_e(x, mode::int)` implements `gsl_sf_airy_Ai_e`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Ai_scaled**

`gsl::sf::airy_Ai_scaled(x, mode::int)` implements `gsl_sf_airy_Ai_scaled`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Ai_scaled_e**

`gsl::sf::airy_Ai_scaled_e(x, mode::int)` implements `gsl_sf_airy_Ai_scaled_e`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Bi**

`gsl::sf::airy_Bi(x, mode::int)` implements `gsl_sf_airy_Bi`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Bi_e**

`gsl::sf::airy_Bi_e(x, mode::int)` implements `gsl_sf_airy_Bi_e`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Bi_scaled**

`gsl::sf::airy_Bi_scaled(x, mode::int)` implements `gsl_sf_airy_Bi_scaled`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Bi_scaled_e**

`gsl::sf::airy_Bi_scaled_e(x, mode::int)` implements `gsl_sf_airy_Bi_scaled_e`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Ai_deriv**

`gsl::sf::airy_Ai_deriv(x, mode::int)` implements `gsl_sf_airy_Ai_deriv`. The first form computes the function with `mode = GSL_PREC_DOUBLE`.

**gsl::sf::airy_Ai_deriv_e**

`gsl::sf::airy_Ai_deriv_e(x, mode::int)` implements `gsl_sf_airy_Ai_deriv`. The first form computes the function with `mode = GSL_PREC_DOUBLE`. 
gsl::sf::airy_Ai_deriv_e(x, mode::int)
  implements gsl_sf_airy_Ai_deriv_e. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Ai_deriv_scaled(x)
gsl::sf::airy_Ai_deriv_scaled(x, mode::int)
  implements gsl_sf_airy_Ai_deriv_scaled. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Ai_deriv_scaled_e(x)
gsl::sf::airy_Ai_deriv_scaled_e(x, mode::int)
  implements gsl_sf_airy_Ai_deriv_scaled_e. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Bi_deriv(x)
gsl::sf::airy_Bi_deriv(x, mode::int)
  implements gsl_sf_airy_Bi_deriv. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Bi_deriv_e(x)
gsl::sf::airy_Bi_deriv_e(x, mode::int)
  implements gsl_sf_airy_Bi_deriv_e. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Bi_deriv_scaled(x)
gsl::sf::airy_Bi_deriv_scaled(x, mode::int)
  implements gsl_sf_airy_Bi_deriv_scaled. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_Bi_deriv_scaled_e(x)
gsl::sf::airy_Bi_deriv_scaled_e(x, mode::int)
  implements gsl_sf_airy_Bi_deriv_scaled_e. The first form computes the function with mode = GSL_PREC_DOUBLE.

gsl::sf::airy_zero_Ai
  implements gsl_sf_airy_zero_Ai.

gsl::sf::airy_zero_Ai_e
  implements gsl_sf_airy_zero_Ai_e.

gsl::sf::airy_zero_Bi
  implements gsl_sf_airy_zero_Bi.

gsl::sf::airy_zero_Bi_e
  implements gsl_sf_airy_zero_Bi_e.

gsl::sf::airy_zero_Ai_deriv
  implements gsl_sf_airy_zero_Ai_deriv.

gsl::sf::airy_zero_Ai_deriv_e
  implements gsl_sf_airy_zero_Ai_deriv_e.
17.2.2 Examples

The following illustrate the Airy functions.

```cpp
> using gsl::sf;
> using namespace gsl::sf;
> airy_Ai (-1.2); // defaults to GSL_PREC_DOUBLE
0.52619437480212
> airy_Ai_scaled (-1.2);
0.52619437480212
> airy_Ai (-1.2,GSL_PREC_APPROX);
0.526194374771687
> airy_Ai_scaled (-1.2, GSL_PREC_SINGLE);
0.526194374771687
> airy_Ai_e (-1.2);
[0.52619437480212,1.88330586480371e-15]
> airy_Ai_e (-1.2,GSL_PREC_APPROX);

0.601710157437464
gsl::sf::bessel_J0 x  
implements gsl_sf_bessel_J0.
gsl::sf::bessel_J0_e x  
implements gsl_sf_besselJ0_e.
gsl::sf::bessel_J1 x  
implements gsl_sf_bessel_J1.
gsl::sf::bessel_J1_e x
   implements gsl_sf_bessel_J1_e.

gsl::sf::bessel_Jn n x
   implements gsl_sf_bessel_Jn.

gsl::sf::bessel_Jn_e n x
   implements gsl_sf_bessel_Jn_e.

gsl::sf::bessel_Jn_array nmin::int nmax::int x
   implements gsl_sf_bessel_Jn_array.

gsl::sf::bessel_Y0 x
   implements gsl_sf_bessel_Y0.

gsl::sf::bessel_Y0_e x
   implements gsl_sf_bessel_Y0_e.

gsl::sf::bessel_Y1 x
   implements gsl_sf_bessel_Y1.

gsl::sf::bessel_Y1_e x
   implements gsl_sf_bessel_Y1_e.

gsl::sf::bessel_Yn x
   implements gsl_sf_bessel_Yn.

gsl::sf::bessel_Yn_e x
   implements gsl_sf_bessel_Yn_e.

gsl::sf::bessel_Yn_array nmin::int nmax::int x
   implements gsl_sf_bessel_Yn_array.

gsl::sf::bessel_I0 x
   implements gsl_sf_bessel_I0.

gsl::sf::bessel_I0_e x
   implements gsl_sf_bessel_I0_e.

gsl::sf::bessel_I1 x
   implements gsl_sf_bessel_I1.

gsl::sf::bessel_I1_e x
   implements gsl_sf_bessel_I1_e.

gsl::sf::bessel_In n::int x
   implements gsl_sf_bessel_In.

gsl::sf::bessel_In_e n::int x
   implements gsl_sf_bessel_In_e.

gsl::sf::bessel_In_array nmin::int nmax::int x
   implements gsl_sf_bessel_In_array.

gsl::sf::bessel_I0_scaled x
   implements gsl_sf_bessel_I0_scaled.
The page contains a list of functions related to Bessel functions, including their implementations in the GSL (GNU Scientific Library). Here are the details:

- **gsl::sf::bessel_I0_scaled_e**
  - Implements `gsl_sf_bessel_I0_scaled_e`.

- **gsl::sf::bessel_I1_scaled**
  - Implements `gsl_sf_bessel_I1_scaled`.

- **gsl::sf::bessel_I1_scaled_e**
  - Implements `gsl_sf_bessel_I1_scaled_e`.

- **gsl::sf::bessel_In_scaled**
  - Implements `gsl_sf_bessel_In_scaled`.

- **gsl::sf::bessel_In_scaled_e**
  - Implements `gsl_sf_bessel_In_scaled_e`.

- **gsl::sf::bessel_In_scaled_array**
  - Implements `gsl_sf_bessel_In_array`.

- **gsl::sf::bessel_K0**
  - Implements `gsl_sf_bessel_K0`.

- **gsl::sf::bessel_K0_e**
  - Implements `gsl_sf_bessel_K0_e`.

- **gsl::sf::bessel_K1**
  - Implements `gsl_sf_bessel_K1`.

- **gsl::sf::bessel_K1_e**
  - Implements `gsl_sf_bessel_K1_e`.

- **gsl::sf::bessel_Kn**
  - Implements `gsl_sf_bessel_Kn`.

- **gsl::sf::bessel_Kn_e**
  - Implements `gsl_sf_bessel_Kn_e`.

- **gsl::sf::bessel_Kn_array**
  - Implements `gsl_sf_bessel_Kn_array`.

- **gsl::sf::bessel_K0_scaled**
  - Implements `gsl_sf_bessel_K0_scaled`.

- **gsl::sf::bessel_K0_scaled_e**
  - Implements `gsl_sf_bessel_K0_scaled_e`.

- **gsl::sf::bessel_K1_scaled**
  - Implements `gsl_sf_bessel_K1_scaled`.

- **gsl::sf::bessel_K1_scaled_e**
  - Implements `gsl_sf_bessel_K1_scaled_e`.

- **gsl::sf::bessel_Kn_scaled**
  - Implements `gsl_sf_bessel_Kn_scaled`.

- **gsl::sf::bessel_Kn_scaled_e**
  - Implements `gsl_sf_bessel_Kn_scaled_e`.

These functions are part of the library documentation for special functions, specifically Bessel functions of the first kind, which are important in various fields of science and engineering.
gsl::sf::bessel_Kn_scaled_array nmin::int nmax::int x
  implements gsl_sf_bessel_Kn_array.

gsl::sf::bessel_j0 x
  implements gsl_sf_bessel_j0.

gsl::sf::bessel_j0_e x
  implements gsl_sf_bessel_j0_e.

gsl::sf::bessel_j1 x
  implements gsl_sf_bessel_j1.

gsl::sf::bessel_j1_e x
  implements gsl_sf_bessel_j1_e.

gsl::sf::bessel_j2 x
  implements gsl_sf_bessel_j2.

gsl::sf::bessel_j2_e x
  implements gsl_sf_bessel_j2_e.

gsl::sf::bessel_jl l::int x
  implements gsl_sf_bessel_jl.

gsl::sf::bessel_jl_e l::int x
  implements gsl_sf_bessel_jl_e.

gsl::sf::bessel_jl_array lmax::int x
  implements gsl_sf_bessel_jl_array.

gsl::sf::bessel_jl_steed_array lmax::int x
  implements gsl_sf_bessel_jl_steed_array.

gsl::sf::bessel_y0 x
  implements gsl_sf_bessel_y0.

gsl::sf::bessel_y0_e x
  implements gsl_sf_bessel_y0_e.

gsl::sf::bessel_y1 x
  implements gsl_sf_bessel_y1.

gsl::sf::bessel_y1_e x
  implements gsl_sf_bessel_y1_e.

gsl::sf::bessel_y2 x
  implements gsl_sf_bessel_y2.

gsl::sf::bessel_y2_e x
  implements gsl_sf_bessel_y2_e.

gsl::sf::bessel_yl l::int x
  implements gsl_sf_bessel_yl.

gsl::sf::bessel_yl_e l::int x
  implements gsl_sf_bessel_yl_e.
gsl::sf::bessel_yl_array lmax::int x
  implements gsl_sf_bessel_yl_array.

gsl::sf::bessel_i0_scaled x
  implements gsl_sf_bessel_i0_scaled.

gsl::sf::bessel_i0_scaled_e x
  implements gsl_sf_bessel_i0_scaled_e.

gsl::sf::bessel_i1_scaled x
  implements gsl_sf_bessel_i1_scaled.

gsl::sf::bessel_i1_scaled_e x
  implements gsl_sf_bessel_i1_scaled_e.

gsl::sf::bessel_i2_scaled x
  implements gsl_sf_bessel_i2_scaled.

gsl::sf::bessel_i2_scaled_e x
  implements gsl_sf_bessel_i2_scaled_e.

gsl::sf::bessel_il_scaled l::int x
  implements gsl_sf_bessel_il_scaled.

gsl::sf::bessel_il_scaled_e l::int x
  implements gsl_sf_bessel_il_scaled_e.

gsl::sf::bessel_il_scaled_array lmax::int x
  implements gsl_sf_bessel_il_scaled_array.

gsl::sf::bessel_k0_scaled x
  implements gsl_sf_bessel_k0_scaled.

gsl::sf::bessel_k0_scaled_e x
  implements gsl_sf_bessel_k0_scaled_e.

gsl::sf::bessel_k1_scaled x
  implements gsl_sf_bessel_k1_scaled.

gsl::sf::bessel_k1_scaled_e x
  implements gsl_sf_bessel_k1_scaled_e.

gsl::sf::bessel_k2_scaled x
  implements gsl_sf_bessel_k2_scaled.

gsl::sf::bessel_k2_scaled_e x
  implements gsl_sf_bessel_k2_scaled_e.

gsl::sf::bessel_kl_scaled l::int x
  implements gsl_sf_bessel_kl_scaled.

gsl::sf::bessel_kl_scaled_e l::int x
  implements gsl_sf_bessel_kl_scaled_e.

gsl::sf::bessel_kl_scaled_array lmax::int x
  implements gsl_sf_bessel_il_scaled_array.
gsl::sf::bessel_Jnu nu x
    implements gsl_sf_bessel_Jnu.

gsl::sf::bessel_Jnu_e nu x
    implements gsl_sf_bessel_Jnu_e.

gsl::sf::bessel_sequence_Jnu_e nu v::matrix
    implements gsl_sf_bessel_sequence_Jnu_e.

gsl::sf::bessel_Ynu nu x
    implements gsl_sf_bessel_Ynu.

gsl::sf::bessel_Ynu_e nu x
    implements gsl_sf_bessel_Ynu_e.

gsl::sf::bessel_Inu nu x
    implements gsl_sf_bessel_Inu.

gsl::sf::bessel_Inu_e nu x
    implements gsl_sf_bessel_Inu_e.

gsl::sf::bessel_Inu_scaled nu x
    implements gsl_sf_bessel_Inu_scaled.

gsl::sf::bessel_Inu_scaled_e nu x
    implements gsl_sf_bessel_Inu_scaled_e.

gsl::sf::bessel_Knu nu x
    implements gsl_sf_bessel_Knu.

gsl::sf::bessel_Knu_e nu x
    implements gsl_sf_bessel_Knu_e.

gsl::sf::bessel_Knu_scaled nu x
    implements gsl_sf_bessel_Knu_scaled.

gsl::sf::bessel_Knu_scaled_e nu x
    implements gsl_sf_bessel_Knu_scaled_e.

gsl::sf::bessel_zero_J0 s::int
    implements gsl_sf_bessel_zero_J0.

gsl::sf::bessel_zero_J0_e s::int
    implements gsl_sf_bessel_zero_J0_e.

gsl::sf::bessel_zero_J1 s::int
    implements gsl_sf_bessel_zero_J1.

gsl::sf::bessel_zero_J1_e s::int
    implements gsl_sf_bessel_zero_J1_e.
gsl::sf::bessel_zero_Jnu nu s::int implements gsl_sf_bessel_zero_Jnu.
gsl::sf::bessel_zero_Jnu_e nu s::int implements gsl_sf_bessel_zero_Jnu.

17.2.4 Examples

The following illustrate the Bessel functions.

```cpp
gsl::sf::bessel_J0 (-1.2); 0.671132744264363
bessel_J0_e 0.75; [0.864242275166649, 7.07329111491049e-16]
```

```cpp

17.2.4 Examples 581
17.2.5 Clausen Functions

\[ \text{gsl::sf::clausen} \]

\[ \text{gsl::sf::clausen}() \]

implements \text{gsl_sf_clausen}.

\[ \text{gsl::sf::clausen}\_e \]

\[ \text{gsl::sf::clausen}\_e() \]

implements \text{gsl_sf_clausen\_e}.

17.2.6 Examples

The following illustrate the Clausen functions.

\[ \text{using gsl::sf;}
\]

\[ \text{using namespace gsl::sf;}
\]

\[ \text{> clausen 4.5;}
\]

\[ -0.831839220823219
\]

\[ \text{> clausen\_e 4.5;}
\]

\[ [-0.831839220823219, 8.60688668835964e-16]
\]

17.2.7 Colomb Functions

The results of the Coulomb wave functions are returned as a list whose elements are ordered corresponding to the argument order of the corresponding C functions in GSL library.

\[ \text{gsl::sf::hydrogenicR\_1} \]

\[ \text{gsl::sf::hydrogenicR\_1\_e} \]

\[ \text{gsl::sf::hydrogenicR} \]

\[ \text{gsl::sf::hydrogenicR\_e} \]

\[ \text{gsl::sf::coulomb\_wave\_FG\_e} \]

\[ \text{gsl::sf::coulomb\_wave\_FG\_array} \]

\[ \text{gsl::sf::coulomb\_wave\_FGp\_array} \]

\[ \text{gsl::sf::coulomb\_wave\_sphF\_array} \]

\[ \text{gsl::sf::coulomb\_CL\_e} \]

implements \text{gsl_sf_hydrogenicR\_1}.

implements \text{gsl_sf_hydrogenicR\_1\_e}.

implements \text{gsl_sf_hydrogenicR}.

implements \text{gsl_sf_hydrogenicR\_e}.

implements \text{gsl_sf_coulomb_wave\_FG\_e}.

implements \text{gsl_sf_coulomb_wave\_FG\_array}.

implements \text{gsl_sf_coulomb_wave\_FGp\_array}.

implements \text{gsl_sf_coulomb_wave\_sphF\_array}.

implements \text{gsl_sf_coulomb_wave\_CL\_e}.

582 17.2 Special Functions
17.2.8 Examples

The following illustrate the Coulomb functions.

```cpp
> using gsl::sf;

```

17.2.9 Coupling Coefficients

```cpp
gsl::sf::coupling_3j m::matrix
  implements gsl_sf_coupling_3j except the input is a 2x3 (row by column) integer
  matrix instead of six integer arguments.

gsl::sf::coupling_3j_e m::matrix
  implements gsl_sf_coupling_3j_e except the input is a 2x3 (row by column) integer
  matrix instead of six integer arguments.

gsl::sf::coupling_6j m::matrix
  implements gsl_sf_coupling_6j except the input is a 2x3 (row by column) integer
  matrix instead of six integer arguments.

gsl::sf::coupling_6j_e m::matrix
  implements gsl_sf_coupling_6j_e except the input is a 2x3 (row by column) integer
  matrix instead of six integer arguments.
```
gsl::sf::coupling_9j m::matrix
   implements gsl_sf_coupling_9j except the input is a 3x3 integer matrix instead of six integer arguments.

gsl::sf::coupling_9j_e m::matrix
   implements gsl_sf_coupling_9j_e except the input is a 3x3 integer matrix instead of six integer arguments.

17.2.10 Examples

The following illustrate the coupling coefficient functions.
>
> using gsl::sf;
> using namespace gsl::sf;
> coupling_3j (6,4,2;0,0,0);
-0.29277002188456
> coupling_3j_e (6,4,2;0,0,0);
[-0.29277002188456,1.300160076865e-16]
> coupling_6j (1,2,3;2,1,2);

```
17.2.15 Dilogarithm

gsl::sf::dilog x
  implements gsl_sf_dilog.

gsl::sf::dilog(r<:theta)
  implements gsl_sf_complex_dilog_e except that results are returned as the complex
  value re+:im and the error values are not returned.

gsl::sf::dilog_e x
  implements gsl_sf_dilog_e.

gsl::sf::dilog_e (r<:theta)
  implements gsl_sf_complex_dilog_e except the results are returned as the list
  [re+:im, re_error, im_error].

17.2.16 Examples

The following illustrate the dilog functions.

> dilog 1.0;
  1.64493406684823

> dilog (1<:2);
  -0.496658586741567+:0.727146050863279

> dilog_e (1%3);
  [0.366213229977064,8.22687466397711e-15]

> dilog_e (1<:3);
  [-0.817454913536463+:0.0980262093913011,3.8224192999699e-15,
   1.47247478976757e-15]

gsl::sf::multiply_e x y
  implements gsl_sf_multiply_e.

gsl::sf::multiply_err_e x dx y dy
  implements gsl_sf_multiply_err_e.

17.2.17 Examples

The following illustrate the multiply functions.

> multiply_e 10.0 11.0;
  [110.0,4.88498130835069e-14]

> multiply_err_e 10.0 0.04 11.0 0.002;
  [110.0,0.460000000000049]
17.3 Matrices

This module is loaded via the command using `gsl::matrix` and provides wrappers for many of the GSL matrix, BLAS, and linear algebra routines found in Chapters 8, 12, and 13, respectively of the GSL Reference Manual:

- Vectors and Matrices
- BLAS Support
- Linear Algebra

It also contains some general utility functions for creating various types of matrices.

17.3.1 Matrix Creation

The utility functions `zeros` and `ones` create matrices with all elements zero or one, respectively, and `eye` creates identity matrices. These functions can be invoked either with a pair $(n,m)$ denoting the desired number of rows or columns, or an integer $n$ in which case a square $n \times n$ matrix is created. The result is always a double matrix. Analogous functions `izeros`, `czeros`, etc. are provided to create integer and complex matrices, respectively.

- `gsl::matrix::zeros(n :: int, m :: int)` creates an $n \times m$ double matrix with all of its entries being zero.
- `gsl::matrix::zeros(n :: int)` creates an $n \times n$ double matrix with all of its entries being zero.
- `gsl::matrix::izeros(n :: int, m :: int)` creates an $n \times m$ integer matrix with all of its entries being zero.
- `gsl::matrix::izeros(n :: int)` creates an $n \times n$ integer matrix with all of its entries being zero.
- `gsl::matrix::czeros(n :: int, m :: int)` creates an $n \times m$ complex matrix with all of its entries being zero.
- `gsl::matrix::czeros(n :: int)` creates an $n \times n$ complex matrix with all of its entries being zero.
- `gsl::matrix::ones(n :: int, m :: int)` creates an $n \times m$ double matrix with all of its entries being one.
- `gsl::matrix::ones(n :: int)` creates an $n \times n$ double matrix with all of its entries being one.
- `gsl::matrix::iones(n :: int, m :: int)` creates an $n \times m$ integer matrix with all of its entries being one.
- `gsl::matrix::iones(n :: int)` creates an $n \times n$ integer matrix with all of its entries being one.
- `gsl::matrix::cones(n :: int, m :: int)` creates an $n \times m$ complex matrix with all of its entries being one.
gsl::matrix::cones n :: int
creates an $n \times n$ complex matrix with all of its entries being one.

gsl::matrix::eye (n :: int, m :: int)
creates an $n \times m$ identity matrix with double entries.

gsl::matrix::eye n :: int
creates an $n \times n$ identity matrix with double entries.

gsl::matrix::ieye (n :: int, m :: int)
creates an $n \times m$ identity matrix with integer entries.

gsl::matrix::ieye n :: int
creates an $n \times n$ identity matrix with integer entries.

gsl::matrix::ceye (n :: int, m :: int)
creates an $n \times m$ identity matrix with complex entries.

gsl::matrix::ceye n :: int
creates an $n \times n$ identity matrix with complex entries.

17.3.2 Matrix Operators and Functions

The following operations are defined for constant $a$ and matrices $x$ and $y$. Some operators are not defined in the GSL library but are provided here for convenience.

$a + x$

$x + a$
returns a matrix with entries $a + x(i,j)$.

$x + y$
adds matrix $x$ to matrix $y$.

$- x$
returns a matrix with entries $- x(i,j)$. Note that $\neg x$ is equivalent to $- x$.

$a - x$
returns a matrix with entries $a - x(i,j)$.

$x - a$
returns a matrix with entries $x(i,j) - a$.

$x - y$
subtracts matrix $y$ from matrix $x$.

$a * x$

$x * a$
returns a matrix with entries $a * x(i,j)$.

$x .* y$
multiplies, element-wise, matrix $x$ to matrix $y$.

$x * y$
multiplies matrix $x$ to matrix $y$. 
a / x
returns a matrix with entries $a / x(i, j)$. Note that matrix $x$ must not have any zero entries.

x / a
returns a matrix with entries $x(i, j) / a$. Note that $a$ must be nonzero.

x ./ y
divides, element-wise, matrix $x$ by matrix $y$.

x / y
right divides matrix $x$ by matrix $y$.

x \ y
left divides matrix $x$ by matrix $y$.

a div x
returns an integer matrix with entries $a \ div x(i, j)$. Note that $a$ must be an integer and matrix $x$ must be an integer matrix with nonzero entries.

x div a
returns an integer matrix with entries $x(i, j) \ div a$. Note that $a$ must be a nonzero integer and matrix $x$ must have integer entries.

x div y
computes the quotient integer matrix $x$ by integer matrix $y$.

a mod x
returns an integer matrix with entries $a \ mod x(i, j)$. Note that $a$ must be an integer and matrix $x$ must be an integer matrix with nonzero entries.

x mod a
returns an integer matrix with entries $a \ mod x(i, j)$. Note that $a$ must be an integer and matrix $x$ must be an integer matrix with nonzero entries.

x mod y
returns the remainder integer matrix $x$ mod integer matrix $y$.

not x
returns a matrix with integer entries not $x(i, j)$. Note that $x$ must be a matrix with integer entries and not is the bitwise negation operation.

a ^ x
returns a matrix with entries $a ^ x(i, j)$. Note that $0^0$ is defined as 1.

x ^ a
returns a matrix with entries $x(i, j) ^ a$. Note that $0^0$ is defined as 1.

x .^ y
returns a matrix with entries $x(i, j) ^ y(i, j)$.

x ^ y
returns a matrix with entries $x(i, j) ^ y(i, j)$.
x << a
returns an integer matrix with entries x!(i,j) << a. Note that a must be an integer and matrix x must have integer entries.

x << y
returns an integer matrix with entries x!(i,j) << y!(i,j). Note that x and y must have integer entries.

x >> a
returns an integer matrix with entries x!(i,j) >> a. Note that a must be an integer and matrix x must have integer entries.

x >> y
returns an integer matrix with entries x!(i,j) >> y!(i,j). Note that x and y must have integer entries.

x and a
a and x
returns an integer matrix with entries a and x!(i,j). Note that a must be an integer, matrix x must have integer entries, and and is a bitwise operator.

x and y
returns an integer matrix with entries x!(i,j) and y!(i,j). Note that x and y must be matrices with integer entries.

x or a
a or x
returns an integer matrix with entries a or x!(i,j). Note that a must be an integer, matrix x must have integer entries, and or is a bitwise operator.

x or y
returns an integer matrix with entries x!(i,j) or y!(i,j). Note that x and y must be matrices with integer entries.

The pow function computes powers of matrices by repeated matrix multiplication.

pow x :: matrix k :: int
pow x :: matrix k :: bigint
    Raises matrix x to the k th power. Note x must be a square matrix and k a nonnegative integer.

17.3.3 Singular Value Decomposition

For a given n x m matrix x, these functions yield a singular-value decomposition u, s, v of the matrix such that x == u*s*transpose v, where u and v are orthogonal matrices of dimensions n x m and n x n, respectively, and s is a n x n diagonal matrix which has the singular values in its diagonal, in descending order. Note that GSL implements this only for double matrices right now. Also, GSL only handles the case of square or overdetermined systems, but we work around that in our wrapper functions by just adding a suitable number of zero rows in the underdetermined case.
gsl::matrix::svd x
    singular-value decomposition of matrix x.

gsl::matrix::svd_mod x
    This uses the modified Golub-Reinsch algorithm, which is faster if n > m but needs O(m^2) extra memory as internal workspace.

gsl::matrix::svd_jacobi x
    This uses one-sided Jacobi orthogonalization which provides better relative accuracy but is slower.

gsl::matrix::svd_solve (u, s, v) b
    Solve the system Ax=b, using the SVD of A. svd_solve takes the result (u, s, v) of a svd call, and a column vector b of the appropriate dimension. The result is another column vector solving the system (possibly in the least-squares sense).

gsl::matrix::pinv x
    Computes the pseudo inverse of a matrix from its singular value decomposition.

17.4 Least-Squares Fitting

This module is loaded via the command using gsl::fit and provides Pure wrappers for the GSL least-squares fitting routines found in Chapter 36 of the GSL manual, http://www.gnu.org/software/gsl/manual/html_node/Least_002dSquares-Fitting.html.

17.4.1 Routines

gsl::fit::linear x::matrix y::matrix
    implements gsl_fit_linear without the xstride, ystride, and n parameters. Results are returned as a list [c0, c1, cov00, cov01, cov11, sumsq].

gsl::fit::wlinear x::matrix w::matrix y::matrix
    implements gsl_fit_wlinear without the xstride, wstride, ystride, and n parameters. Results are given as a list [c0, c1, cov00, cov01, cov11, chisq].

gsl::fit::linear_est x c0::double c1::double cov00::double cov01::double cov11::double
    implements gsl_fit_linear_est. Results are returned as a list [y, y_err].

gsl::fit::mul x::matrix y::matrix
    implements gsl_fit_mul omitting the parameters xstride, ystride, and n. Results are returned as a list [c1, cov11, sumsq].

gsl::fit::wmul x::matrix w::matrix y::matrix
    implements gsl_fit_wmul omitting the parameters xstride, ystride, and n. Results are returned as a list [c1, cov11, sumsq].

gsl::fit::mul_est x c1::double cov11::double
    implements gsl_fit_mul_est. Results are returned as a list [y, y_err].
17.4.2 Examples

Usage of each implemented library routine is illustrated below.

```c
> using gsl::fit;
> using namespace gsl::fit;
```

The following code determines the equation for the least-squares line through the points (1,0.01), (2,1.11), (3,1.9), (4,2.85), and (5,4.01).

```c
> Y x = '(a + b * x)
> when
>   a:b:_ = linear {1,2,3,4,5} {0.01,1.11,1.9,2.85,4.01}
> end;
> Y x;
-0.946+0.974*x
> eval $ Y 2;
1.002
```

The following code illustrates estimating y-values without constructing an equation for the least-squares line determined by the points \(\{x_1, x_2, x_3, \ldots, x_n\}, \{y_1, y_2, y_3, \ldots, y_n\}\). Here we estimate the y-value at \(x = 1\), \(x = 2\), and \(x = 3\). Compare the output above at \(x = 2\) to the output at \(x = 2\) below.

```c
> let c0:c1:cov00:cov01:cov11:_ = linear {1,2,3,4,5}
>   {0.01,1.11,1.9,2.85,4.01};
> linear_est 1 c0 c1 cov00 cov01 cov11;
[0.028,0.0838570211729465]
> linear_est 2 c0 c1 cov00 cov01 cov11;
[1.002,0.0592958683214944]
> linear_est 3 c0 c1 cov00 cov01 cov11;
[1.976,0.0484148737476408]
```

Next, we determine a least-squares line through the points (1,0.01), (2,1.11), (3,1.9), (4,2.85), and (5,4.01) using weights 0.1, 0.2, 0.3, 0.4, and 0.5.

```c
> W x = '(a + b * x)
> when
>   a:b:_ = wlinear (matrix {1..5})
>   {0.1, 0.2, 0.3, 0.4, 0.5}
> end;
> W u;
-0.99+0.986*u
> eval $ W 2;
0.982
```

The least-squares slope for \(Y = c_1 \times X\) using the points (1,3), (2,5), and (3,7) is calculated below. Also, the y-values and standard error about \(x = 1, 2,\) and \(3\) are given.

```c
> let c1:cov11:sumsq:_ = mul {1,2,3} {3,5,7};
> mul_est 1 c1 cov11;
[2.42857142857143,0.123717914826348]
```
The least-squares slope for $Y = c_1 \times X$ using the points (1,3), (2,5), and (3,7), and weights 0.4, 0.9, and 0.4 is calculated below. The approximation of y-values and standard error about $x = 1, 2, \text{and } 3$ follows.

```plaintext
> let c1:cov11:sumsq:_ = wmul {1,2,3} {0.4,0.9,0.4} {3,5,7};
> mul_est 1 c1 cov11;
[2.44736842105263,0.362738125055006]
> mul_est 2 c1 cov11;
[4.89473684210526,0.725476250110012]
> mul_est 3 c1 cov11;
[7.34210526315789,1.08821437516502]
```

## 17.5 Statistics

This module is loaded via the command using `gsl::stats` and provides Pure wrappers for the GSL Statistics routines found in Chapter 20 of the GSL manual, http://www.gnu.org/software/gsl/manual/html_node/Statistics.html.

### 17.5.1 Routines

- `gsl::stats::mean` data::matrix
  implements `gsl_stats_mean` without stride and n arguments.

- `gsl::stats::variance` data::matrix
  implements `gsl_stats_variance` without stride and n arguments.

- `gsl::stats::variance` data::matrix mean
  implements `gsl_stats_variance_m` without stride and n arguments.

- `gsl::stats::sd` data::matrix
  implements `gsl_stats_sd` without stride and n arguments.

- `gsl::stats::sd_m` data::matrix mean
  implements `gsl_stats_sd_m` without stride and n arguments.

- `gsl::stats::tss` data::matrix
  implements `gsl_stats_tss` without stride and n arguments.

- `gsl::stats::tss_m` data::matrix mean
  implements `gsl_stats_tss_m` without stride and n arguments.

- `gsl::stats::variance_with_fixed_mean` data::matrix mean
  implements `gsl_stats_variance_with_fixed_mean` without stride and n arguments.

- `gsl::stats::sd_with_fixed_mean` data::matrix mean
  implements `gsl_stats_sd_with_fixed_mean` without stride and n arguments.
gsl::stats::absdev data::matrix
    implements gsl_stats_absdev without stride and n arguments.
gsl::stats::absdev_m data::matrix mean
    implements gsl_stats_absdev_m without stride and n arguments.
gsl::stats::skew data::matrix mean
    implements gsl_stats_skew without stride and n arguments.
gsl::stats::skew_m_sd data::matrix mean sd
    implements gsl_stats_skew_m_sd without stride and n arguments.
gsl::stats::kurtosis data::matrix
    implements gsl_stats_kurtosis without stride and n arguments.
gsl::stats::kurtosis_m_sd data::matrix mean sd
    implements gsl_stats_kurtosis_m_sd without stride and n arguments.
gsl::stats::lag1_autocorrelation data::matrix
    implements gsl_stats_lag1_autocorrelation without stride and n arguments.
gsl::stats::lag1_autocorrelation_m data::matrix mean
    implements gsl_stats_lag1_autocorrelation_m without stride and n arguments.
gsl::stats::covariance d1::matrix d2::matrix
    implements gsl_stats_covariance without stride1, stride2, and n arguments.
gsl::stats::covariance_m d1::matrix d2::matrix mean1 mean2
    implements gsl_stats_covariance_m without stride1, stride2, and n arguments.
gsl::stats::correlation d1::matrix d2::matrix
    implements gsl_stats_correlation without stride1, stride2, and n arguments.
gsl::stats::wmean weight::matrix data::matrix
    implements gsl_stats_wmean without stride and n arguments.
gsl::stats::wvariance weight::matrix data::matrix
    implements gsl_stats_wvariance without stride and n arguments.
gsl::stats::wvariance_m weight::matrix data::matrix mean
    implements gsl_stats_wvariance_m without stride and n arguments.
gsl::stats::wsd weight::matrix data::matrix
    implements gsl_stats_wsd without stride and n arguments.
gsl::stats::wsd_m weight::matrix data::matrix mean
    implements gsl_stats_wsd_m without stride and n arguments.
gsl::stats::wvariance_with_fixed_mean weight::matrix data::matrix mean
    implements gsl_stats_wvariance_with_fixed_mean without stride and n arguments.
gsl::stats::wsd_with_fixed_mean weight::matrix data::matrix mean
    implements gsl_stats_wsd_with_fixed_mean without stride and n arguments.
gsl::stats::wtss weight::matrix data::matrix
   implements gsl_stats_wtss without stride and n arguments.

gsl::stats::wtss_m weight::matrix data::matrix mean
   implements gsl_stats_wtss_m without stride and n arguments.

gsl::stats::wabsdev weight::matrix data::matrix
   implements gsl_stats_wabsdev without stride and n arguments.

gsl::stats::wabsdev_m weight::matrix data::matrix mean
   implements gsl_stats_wabsdev_m without stride and n arguments.

gsl::stats::wskew weight::matrix data::matrix
   implements gsl_stats_wskew without stride and n arguments.

gsl::stats::wskew_m_sd weight::matrix data::matrix mean sd
   implements gsl_stats_wskew_m_sd without stride and n arguments.

gsl::stats::wkurtosis weight::matrix data::matrix
   implements gsl_stats_wkurtosis without stride and n arguments.

gsl::stats::wkurtosis_m_sd weight::matrix data::matrix
   implements gsl_stats_wkurtosis_m_sd without stride and n arguments.

gsl::stats::max data::matrix
   implements gsl_stats_max without stride and n arguments.

gsl::stats::min data::matrix
   implements gsl_stats_min without stride and n arguments.

gsl::stats::minmax data::matrix
   implements gsl_stats_minmax without stride and n arguments. Results are returned as a list [min, max].

gsl::stats::min_index data::matrix
   implements gsl_stats_min_index without stride and n arguments.

gsl::stats::max_index data::matrix
   implements gsl_stats_max_index without stride and n arguments.

gsl::stats::minmax_index data::matrix
   implements gsl_stats_minmax_index without stride and n arguments. Results are returned as a list [min_index, max_index].

gsl::stats::median_from_sorted_data data::matrix
   implements gsl_stats_median_from_sorted_data without stride and n arguments.

gsl::stats::quantile_from_sorted_data data::matrix f::double
   implements gsl_stats_quantile_from_sorted_data without stride and n arguments.

17.5.2 Examples

The following illustrates the use of each function in the stats module.
> using gsl::stats;
> using namespace gsl::stats;
> mean {1,2,3,4,5};
3.0
> variance {1,2,3,4,5};
2.5
> variance_m {1,2,3,4,5} 4;
3.75
> sd {1,2,3,4,5};
1.5811383088419
> sd_m {1,2,3,4,5} 4;
1.93649167310371
> tss {1,2,3,4,5};
10.0
> tss_m {1,2,3,4,5} 4;
15.0
> variance_with_fixed_mean {0.0,1.2,3.4,5.6,6.0} 4.1;
6.314
> sd_with_fixed_mean {0.0,1.2,3.4,5.6,6.0} 4.1;
2.51276739870606

17.6 Random Number Distributions

This module is loaded via the command using gsl::randist and provides Pure wrappers for the GSL random distribution routines found in Chapter 19 of the GSL manual, http://www.gnu.org/software/gsl/manual/html_node/Random-Number-Distributions.html.

There are two namespaces provided by randist.pure, gsl::ran for probability density functions and gsl::cdf for cumulative distribution functions. The two namespaces minimize typing of the prefixes gsl_ran_ and gsl_cdf_ respectively.
17.6.1 Routines

```cpp
#include <gsl/gsl_ran.h>

// UGAUSSIAN DISTRIBUTION
double ugaussian_pdf(double x)
{
    return gsl_ran_ugaussian_pdf(r, mu);
}

// GAUSSIAN DISTRIBUTION
double gaussian_pdf(double x, double sigma)
{
    return gsl_ran_gaussian_pdf(r, sigma);
}

// GAUSSIAN TAIL DISTRIBUTION
double gaussian_tail_pdf(double x, double a, double sigma)
{
    return gsl_ran_gaussian_tail_pdf(r, a, sigma);
}

// UGAUSSIAN TAIL DISTRIBUTION
double ugaussian_tail_pdf(double x, double a)
{
    return gsl_ran_ugaussian_tail_pdf(r, a);
}

// BIVARIATE GAUSSIAN DISTRIBUTION
double bivariate_gaussian_pdf(double x, double a, double b)
{
    return gsl_ran_bivariate_gaussian_pdf(r, a, b);
}

// EXPONENTIAL DISTRIBUTION
double exponential_pdf(double x, double mu)
{
    return gsl_ran_exponential_pdf(r, mu);
}

// LAPLACE DISTRIBUTION
double laplace_pdf(double x, double a)
{
    return gsl_ran_laplace_pdf(r, a);
}

// EXP-Power DISTRIBUTION
double exppow_pdf(double x, double a, double b)
{
    return gsl_ran_exppow_pdf(r, a, b);
}

// CAUCHY DISTRIBUTION
double cauchy_pdf(double x, double a)
{
    return gsl_ran_cauchy_pdf(r, a);
}

// RAYLEIGH DISTRIBUTION
double rayleigh_pdf(double x, double sigma)
{
    return gsl_ran_rayleigh_pdf(r, sigma);
}

// RAYLEIGH TAIL DISTRIBUTION
double rayleigh_tail_pdf(double x, double a, double sigma)
{
    return gsl_ran_rayleigh_tail_pdf(r, a, sigma);
}

// LANDAU DISTRIBUTION
double landau_pdf(double x)
{
    return gsl_ran_landau_pdf(r, x);
}

// GAMMA DISTRIBUTION
double gamma_pdf(double x, double a, double b)
{
    return gsl_ran_gamma_pdf(r, a, b);
}

// FLAT DISTRIBUTION
double flat_pdf(double x, double a, double b)
{
    return gsl_ran_flat_pdf(r, a, b);
}

// LOGNORMAL DISTRIBUTION
double lognormal_pdf(double x, double zeta, double sigma)
{
    return gsl_ran_lognormal_pdf(r, zeta, sigma);
}

// CHI-SQUARE DISTRIBUTION
double chisq_pdf(double x, double nu)
{
    return gsl_ran_chisq_pdf(r, nu);
}

// F-DISTRIBUTION
double fdist_pdf(double x, double nu1, double nu2)
{
    return gsl_ran_fdist_pdf(r, nu1, nu2);
}

// T-DISTRIBUTION
double tdist_pdf(double x, double nu)
{
    return gsl_ran_tdist_pdf(r, nu);
}
```
gsl::ran::beta_pdf x a b
  implements gsl_ran_beta_pdf.

gsl::ran::logistic_pdf x a
  implements gsl_ran_logistic_pdf.

gsl::ran::pareto_pdf x a b
  implements gsl_ran_pareto_pdf.

gsl::ran::weibull_pdf x a b
  implements gsl_ran_weibull_pdf.

gsl::ran::gumbell_pdf x a b
  implements gsl_ran_gumbell_pdf.

gsl::ran::gumbel2_pdf x a b
  implements gsl_ran_gumbel2_pdf.

gsl::ran::dirichlet_pdf alpha::matrix theta::matrix
  implements gsl_ran_dirichlet_pdf.

gsl::ran::dirichlet_lnpdf alpha::matrix theta::matrix
  implements gsl_ran_dirichlet_lnpdf.

gsl::ran::discrete_preproc p::matrix
  implements gsl_ran_discrete_preproc without the K parameter.

gsl::ran::discrete_pdf k::int p::pointer
  implements gsl_ran_discrete_pdf without the K parameter.

gsl::ran::discrete_free p::pointer
  implements gsl_ran_discrete_free

gsl::ran::poisson_pdf k::int mu
  implements gsl_ran_poisson_pdf.

gsl::ran::bernoulli_pdf k::int p
  implements gsl_ran_bernoulli_pdf.

gsl::ran::binomial_pdf k::int p n::int
  implements gsl_ran_binomial_pdf.

gsl::ran::multinomial_pdf p::matrix n::matrix
  implements gsl_ran_multinomial_pdf.

gsl::ran::multinomial_lnpdf p::matrix n::matrix
  implements gsl_ran_multinomial_lnpdf.

gsl::ran::negative_binomial_pdf k::int p n
  implements gsl_ran_negative_binomial_pdf.

gsl::ran::pascal_pdf k::int p n::int
  implements gsl_ran_pascal_pdf.

gsl::ran::geometric_pdf k::int p
  implements gsl_ran_geometric_pdf.
gsl::ran::hypergeometric_pdf k::int n1::int n2::int t::int
    implements gsl_ran_hypergeometric_pdf.

gsl::ran::logarithmic_pdf k::int p
    implements gsl_ran_logarithmic_pdf.

gsl::cdf::ugaussian_P x
    implements gsl_cdf_ugaussian_P.

gsl::cdf::ugaussian_Q x
    implements gsl_cdf_ugaussian_Q.

gsl::cdf::ugaussian_Pinv p
    implements gsl_cdf_ugaussian_Pinv.

gsl::cdf::ugaussian_Qinv q
    implements gsl_cdf_ugaussian_Qinv.

gsl::cdf::gaussian_P x sigma
    implements gsl_cdf_gaussian_P.

gsl::cdf::gaussian_Q x sigma
    implements gsl_cdf_gaussian_Q.

gsl::cdf::gaussian_Pinv p sigma
    implements gsl_cdf_gaussian_Pinv.

gsl::cdf::gaussian_Qinv q sigma
    implements gsl_cdf_gaussian_Qinv.

gsl::cdf::exponential_P x mu
    implements gsl_cdf_exponential_P.

gsl::cdf::exponential_Q x mu
    implements gsl_cdf_exponential_Q.

gsl::cdf::exponential_Pinv p mu
    implements gsl_cdf_exponential_Pinv.

gsl::cdf::exponential_Qinv q mu
    implements gsl_cdf_exponential_Qinv.

gsl::cdf::laplace_P x a
    implements gsl_cdf_laplace_P.

gsl::cdf::laplace_Q x a
    implements gsl_cdf_laplace_Q.

gsl::cdf::laplace_Pinv p a
    implements gsl_cdf_laplace_Pinv.

gsl::cdf::laplace_Qinv q a
    implements gsl_cdf_laplace_Qinv.

gsl::cdf::exppow_P x a b
    implements gsl_cdf_exppow_P.
gsl::cdf::exppow_Q x a b

17.7 Sorting

This module is loaded via the command using gsl::sort and provides Pure wrappers for the GSL sorting routines found in Chapter 11 of the GSL manual,

17.7.1 Routines

gsl::sort_vector m::matrix
    implements gsl_sort and gsl_sort_int without stride and n parameters.

17.7.2 Examples

Usage of each library routine is illustrated below.

> using gsl::sort;
> using namespace gsl;
> sort_vector {0,3,2,4,5};
{0,2,3,4,5}
> sort_vector_index {0.0,1.0,5.0,2.0,8.0,0.0};
{5,0,1,3,2,4}
The GNU MPFR library is a C library for multiple-precision floating-point computations with correct rounding. It is based on GMP which Pure also uses for its bigint support.

This module makes the MPFR multiprecision floats (henceforth referred to as mpfr numbers or values) available in Pure, so that they work with the other types of Pure numbers in an almost seamless fashion. Pure mpfr values are represented as pointers which can readily be passed as arguments to the MPFR functions, so the representation only involves minimal overhead on the Pure side.

The module defines the type of mpfr values as an instance of Pure’s real type, so that it becomes a well-behaved citizen of Pure’s numeric tower. Memory management of these values is automatic. You can create an mpfr value from any other kind of Pure real value (int, bigint or double), or from a string in decimal notation, using the mpfr function. Back conversions are provided from mpfr to int, bigint, double and string (the latter by means of a custom pretty-printer installed by this module, so that mpfr values are printed in a format similar to the printf %g format). Integration with Pure’s complex type is provided as well.

Please note that this module needs more testing and the API hasn’t been finalized yet, but it should be perfectly usable already. As usual, please report any bugs on the Pure issue tracker, on the Pure mailing list, or directly to the author, see http://purelang.bitbucket.org/.

18.1 Copying

Copyright (c) 2011 by Albert Graef.

pure-mpfr is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either
version 3 of the License, or (at your option) any later version.
pure-mpfr is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY;
without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.
You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

18.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-mpfr-0.5.tar.gz.

Run `make` to compile the module and `make install` (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure and libmpfr installed.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually, please check the Makefile for details.

Note: This module requires Pure 0.50 or later and libmpfr 3.x (3.0.0 has been tested). Older libmpfr versions (2.x) probably require some work.

18.3 Usage

After installation, you can use the operations of this module by placing the following import declaration in your Pure programs:

```pure
using mpfr;
```

Note: This also pulls in the `math` standard library module, whose operations are overloaded by the `mpfr` module in order to provide support for `mpfr` values. Thus you don’t need to explicitly import the `math` module when using the `mpfr` module.

If you use both the `mpfr` module and the `pointers` standard library module in your script, make sure that you import the `pointers` module after `mpfr`, so that the definitions of pointer arithmetic in the `pointers` module do not interfere with the overloading of arithmetic operations in the `mpfr` module.

18.3.1 Precision and Rounding

The following operations of the MPFR library are provided to inspect and change the default precision and rounding modes used by MPFR.

```pure
mpfr_get_default_prec
```
**mpfr_set_default_prec** prec

Get and set the default precision in terms of number of bits in the mantissa, including the sign. MPFR initially sets this to 53 (matching the mantissa size of double values). It can be changed to any desired value not less than 2.

**mpfr_get_prec** x

Get the precision of an mpfr number x. Note that mpfr numbers always keep the precision they were created with, but it is possible to create a new mpfr number with any given precision from an existing mpfr number using the mpfr function, see below.

**mpfr_get_default_rounding_mode**

**mpfr_set_default_rounding_mode** rnd

Get and set the default rounding mode, which is used for all arithmetic operations and mathematical functions provided by this module. The given rounding mode rnd must be one of the supported rounding modes listed below.

- **constant MPFR_RNDN** // round to nearest, with ties to even
- **constant MPFR_RNDZ** // round toward zero
- **constant MPFR_RNDU** // round toward +Inf
- **constant MPFR_RNDD** // round toward -Inf
- **constant MPFR_RNDA** // round away from zero

Supported rounding modes. Please check the MPFR documentation for details.

In addition, the following operations enable you to control the precision in textual representations of mpfr values. This information is used by the custom pretty-printer for mpfr values installed by the module.

**mpfr_get_print_prec**

**mpfr_set_print_prec** prec

Get and set the precision (number of decimal digits in the mantissa) used by the pretty-printer.

### 18.3.2 MPFR Numbers

The module defines the following data type for representing mpfr values, which is a subtype of the Pure real type:

**type mpfr**

This is a tagged pointer type (denoted mpfr* in Pure extern declarations) which is compatible with the mpfr_t and mpfr_ptr data types of the MPFR C library. Members of this type are “cooked” pointers, which are allocated dynamically and freed automatically when they are garbage-collected (by means of a corresponding Pure sentry).

**mpfrp x**

Type predicate checking for mpfr values.

### 18.3.3 Conversions

The following operations are provided to convert between mpfr numbers and other kinds of Pure real values.
This function converts any real number (int, bigint, double, rational, mpfr) to an mpfr value.

Optionally, it is possible to specify a precision (number of bits in the mantissa) prec and a rounding mode rnd (one of the MPFR_RND constants), otherwise MPFR’s default precision and rounding mode are used (see Precision and Rounding above). Note that this function may also be used to convert an mpfr to a new mpfr number, possibly with a different precision and rounding.

The argument x can also be a string denoting a floating point number in decimal notation with optional sign, decimal point and/or scaling factor, which is parsed and converted to an mpfr number using the corresponding MPFR function.

Convert an mpfr number x to the corresponding type of real number. Please note that there is no rational conversion, as MPFR does not provide such an operation, but if you need this then you can first convert x to a double and then apply the standard library rational function to it (this may loose precision, of course).

By virtue of the custom pretty-printer provided by this module, the standard library str function can be used to obtain a printable representation of an mpfr number x in decimal notation. The result is a string.

Rounding and truncation functions. These all take and yield mpfr numbers. frac returns the fractional part of an mpfr number, i.e., x-trunc x.

18.3.4 Arithmetic

The following standard operators (see the Pure Library Manual) are overloaded to provide mpfr arithmetic and comparisons. These all handle mixed mpfr/real operands.

Arithmetic operations.
Comparisons.

18.3.5  Math Functions

The following functions from the `math` module are overloaded to provide support for `mpfr` values. Note that it is also possible to invoke the corresponding functions from the MPFR library in a direct fashion, using the same function names with an additional `_mpfr` suffix. These functions also accept other kinds of real arguments which are converted to `mpfr` before applying the MPFR function.

```
abs x
  Absolute value (this is implemented directly, so there’s no corresponding `_mpfr` function for this).
sqrt x
exp x
ln x
log x
  Square root, exponential and logarithms.
sin x
cos x	an x
asin x
acos x
atan x
atan2 y x
  Trigonometric functions.
sinh x
cosh x	anh x
asinh x
acosh x
atanh x
  Hyperbolic trigonometric functions.
```

18.3.6  Complex Number Support

The following functions from the `math` module are overloaded to provide support for complex values involving `mpfr` numbers:

```
complex x
```
18.4 Examples

Import the module and set the default precision:

```plaintext
> using mpfr;
> mpfr_set_default_prec 64; // extended precision (long double on x86)
()
```

Calculate π with the current precision. Note that mixed arithmetic works with any combination of real and mpfr numbers.

```plaintext
> let Pi = 4*atan (mpfr 1);
> pi, Pi; abs (Pi-pi);
3.14159265358979
3.14159265358979323851
1.22514845490862001043e-16
```

```plaintext
> let Pi2 = Pi^2;
> Pi2; sqrt Pi2; sqrt Pi2 == Pi;
9.86960440108935861941
3.14159265358979323851
1
```

You can also query the precision of a number and change it on the fly:

```plaintext
> Pi; mpfr_get_prec Pi;
3.14159265358979323851
64
> let Pi1 = mpfr (Pi,53); Pi1; mpfr_get_prec Pi1;
3.1415926535897931
53
```

Complex mpfr numbers work, too:

```plaintext
> let z = mpfr 2^(1/i); z;
0.769238901363972126565+:0.638961276313634801184
> let z = ln z/ln (mpfr 2); z;
0.0+-1.0
> abs z, arg z;
1.0,-1.57079632679489661926
> polar z;
1.0<:-1.57079632679489661926
```
Chapter 19

pure-octave

Version 0.12, August 21, 2019
Albert Graef <aggraef@gmail.com>
A Pure interface to GNU Octave.

19.1 Introduction

This is an Octave module for the Pure programming language, based on Paul Kienzle’s octave_embed which allows Octave to be embedded in other languages. It allows you to execute arbitrary Octave commands and Octave functions from Pure.

19.2 Copying

pure-octave is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-octave is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

Please see the accompanying COPYING file for the precise license terms. The GPL can also be read online at http://www.gnu.org/licenses/.

19.3 Installation

Run make to compile the module and make install (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have both Pure and Oc-
Pure Language and Library Documentation, Release 0.68

tave installed (including Octave’s mkoctfile utility and the corresponding header files and libraries).

make tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, make install prefix=/usr sets the installation prefix. Please see the Makefile for details.

This release of pure-octave has been tested and is known to work with Octave 3.6.2, 3.8, 4.0, 4.4, and 5.1. Older versions might require some fiddling with the sources to get the embedded Octave interface working.

NOTE: The embedded interpreter is broken with Octave 4.2, so make sure that you got a later version, or use one of the known good earlier versions listed above.

19.4 Basic Usage

Import this module into your Pure scripts as follows:

```
using octave;
```

This will add an embedded instance of the Octave interpreter to your program. (You can import this module as often as you want, but there’s always only one instance of Octave in each process.)

```
octave_eval "eig([1 2;3 4])"
```

```
ans =

-0.37228
 5.37228
```

0

This prints the result on stdout and returns a result code (zero if everything went fine). To suppress the printing of the result, simply terminate the Octave statement with a semicolon:

```
> octave_eval "eig([1 2;3 4]);"
```

0

```
octave_set var val
octave_get var
```

Set and get global variables in the Octave interpreter.

This allows you to define values to be used when evaluating Octave code, and to transfer results back to Pure. However, before such globals can be accessed in Octave, you must explicitly declare them as globals:

```
> octave_eval "global x y ans"
```

0
Now you can use `octave.set` and `octave.get` to transfer values between Pure and Octave as follows:

```plaintext
> octave_set "x" {1.0,2.0;3.0,4.0};
(1.0,2.0;3.0,4.0)
> octave_eval "eig(x);"
0
> octave_get "ans";
{-0.372281323269014;5.37228132326901}
```

Note that the most recent result can always be accessed through Octave’s `ans` variable. You can also use an explicit variable definition as follows:

```plaintext
> octave_eval "y = eig(x);"
0
> octave_get "y";
{-0.372281323269014;5.37228132326901}
```

### 19.5 Direct Function Calls

**octave.call** fun n args

Call an octave function in a direct fashion. `fun` denotes the name of the function, `n` the number of function results and `args` the function arguments.

```plaintext
> let x = {1.0,2.0;3.0,4.0};
> octave_call "eig" 1 x;
{-0.372281323269014;5.37228132326901}
```

Note the second argument, which denotes the desired number of return values. This will usually be 1 (or 0 if you don’t care about the result), but some Octave functions may return a variable number of results, depending on how they’re called. Multiple values are returned as tuples in Pure:

```plaintext
> octave_call "eig" 2 x;
{-0.824564840132394,-0.415973557919284;0.565767464968992,-0.909376709132124},
{-0.372281323269014;0.0;0.0,5.37228132326901}
```

Multiple arguments are also specified as a tuple:

```plaintext
> octave_call "norm" 1 (x, 2);
5.46498570421904
> octave_call "norm" 1 (x, 1);
6.0
```

Instead of a function name, you can also specify the function to be called using a special kind of Octave object, a function value. These are returned, e.g., by Octave’s `str2func` and `inline` builtins. For your convenience, pure-octave provides a frontend to these builtins, the `octave_func` function, which lets you specify an Octave function in one of two ways:

**octave.func** name

Returns the Octave function with the given name. This works like Octave’s `str2func`
PCLibrary Documentation, Release 0.68

**builtin.**

**octave_func expr**

Returns an “inline” function, where expr is an Octave expression (as a string) describing the function value. This works like Octave’s **inline** builtin. Instead of just an Octave expression, you can also specify a tuple consisting of the inline expression and the parameter names. (Otherwise the parameters are determined automatically, see the description of the **inline** function in the Octave manual for details.)

Note that inline functions allow you to call stuff that is not an Octave function and hence cannot be specified directly in **octave_call**, such as an operator. Examples:

```octave
> let eig = octave_func "eig";
> let mul = octave_func "x*y";
> octave_call eig 1 (octave_call mul 1 (x,x));
{0.138593383654928;28.8614066163451}
> let add = octave_func ("x+y","x","y");
> octave_call add 1 (x,x);
{2.0,4.0;6.0,8.0}
```

### 19.6 Data Conversions

As shown above, the **octave_set**, **octave_get** and **octave_call** functions convert Pure data to corresponding Octave values and vice versa. Octave scalars and matrices of boolean, integer, double, complex and character data are all directly supported by this interface, and are mapped to the corresponding Pure data types in a straightforward manner (scalars to scalars, matrices to matrices and strings to strings). Note that in any case these conversions create copies of the data, so modifying, say, an Octave matrix received via **octave_get** in Pure only affects the Pure copy of the matrix and leaves the original Octave matrix unchanged.

Octave’s higher-dimensional numeric arrays, cell arrays and structures are not natively supported by the interface, but are implemented using special conversion hooks defined in the octave.pure module (see the **__pure2oct** and **__oct2pure** functions in octave.pure). This simplifies the implementation and makes these conversions customizable if the need arises. It also makes it possible to extend the interface for further special data structures in the future. Please check the octave.pure module for details. It’s possible to disable these custom conversions with the **octave_converters** function:

**octave_converters** flag

Enable or disable custom data conversions between Pure and Octave. The given flag must be a truth value (zero means disable, any nonzero value enable). The function returns the previous value of the flag.

Octave objects which are neither handled natively by the interface nor through the auxiliary converters (if enabled) are just passed through as is, in the form of a cooked pointer to an Octave value which frees itself when garbage-collected. This allows these objects to be passed around freely, but you can’t inspect or modify them in Pure. This applies, in particular, to Octave function objects, see Direct Function Calls. You can check for such objects with the **octave_valuep** predicate:
octave_valuep

Check for Octave value pointers.

> let eig = octave_func "eig";
> eig; octave_valuep eig;
#<pointer 0x230dba0>
1

Such Octave value pointers can be used freely wherever an Octave value is needed (i.e., in
invocations of octave_set and octave_call).

You should also note the following:

- Scalars and 1x1 matrices are indistinguishable in Octave, thus any 1x1 matrix will be
  returned as a scalar from Octave to Pure.

- All types of boolean and integer matrices are returned from Octave to Pure as (ma-
  chine) integer matrices. When converted back to Octave, these all become Octave
  int32 matrices, but you can easily convert them to boolean or other types of matri-
  ces in Octave as needed. For instance:

  > octave_set "a" {1,2;3,4};
  {1,2;3,4}
  > octave_eval "global a ans";
  0
  > octave_eval "eig(a)";
  error: eig: wrong type argument 'int32 matrix'
  1
  > octave_eval "eig(double(a))";
  ans =
   -0.37228
   5.37228

  0
  > octave_eval "a>2";
  ans =
    0 0
    1 1

  0
  > octave_get "ans";
  {0,0;1,1}

- Octave strings are mapped to Pure strings, and character matrices with more than one
  row are mapped to (symbolic) column vectors of Pure strings. Example:

  > octave_set "a" "Hello, world!";
  "Hello, world!"
  > octave_eval "a";
  a = Hello, world!
  0

 19.6 Data Conversions

621
Pure Language and Library Documentation, Release 0.68

> octave_eval "[a;'abc']";
ans =
Hello, world!
abc
0
> octave_get "ans";
{"Hello, world!";'abc "}

• With the default converters, Octave numeric and cell arrays are represented as symbolic Pure matrices, structs as Pure records. This is still experimental and minor details of the Pure data representations are subject to change; please check octave.pure for more information. Here are some examples:

> octave_call "rand" 1 (1,2,3);
{{0.775409654288678,0.946392719372485,0.351919625087157},
{0.388835562237807,0.589476406910984,0.839694088469728}}
> octave_call "size" 1 ans;
{1.0,2.0,3.0}

> octave_eval "struct('name', 'Peter', 'age', 23);"; octave_get "ans";
0
{"name"=>"Peter","age"=>23.0}
> octave_call (octave_func ("x.age","x")) 1 ans;
23.0

Nested cell arrays and structs are set off with the special cell and struct constructors:

> octave_eval "x = {[1,2,3], {1,2,3}}; x{3}.name = 'Peter'; x{3}.age = 23;";
0
> octave_get "x";
{{1.0,2.0,3.0},cell {1.0,2.0,3.0},struct{"name"=>"Peter","age"=>23.0}}

Struct arrays are also supported:

> octave_eval "y = struct('name', {'Peter','Hannah'}, 'age', {23, 16});";
0
> octave_get "y";
{"name"=>"Peter","age"=>23.0},{"name"=>"Hannah","age"=>16.0}

There's also a little convenience function to factor a struct array into a more condensed form (this format can also be used to denote a struct array in Pure):

> struct_array ans;
{"name"=>{"Peter","Hannah"},"age"=>{23.0,16.0}}
> octave_call "disp" 0 ans;

1x2 struct array containing the fields:

   name
   age

19.6 Data Conversions
19.7 Calling Back Into Pure

The embedded Octave interpreter provides one special builtin, the `pure_call` function which can be used to call any function defined in the executing Pure script from Octave. For instance:

```octave
> even m::matrix = {~(int x mod 2) | x=m};
> octave_eval "pure_call('even', 1:12)"
ans =
0 1 0 1 0 1 0 1 0 1 0 1
```

Here's the description of the `pure_call` function, as it is printed with Octave's `help` command:

'pure_call' is a built-in function

```octave
RES = pure_call(NAME, ARG, ...)
[RES, ...] = pure_call(NAME, ARG, ...)
```

Execute the Pure function named NAME (a string) with the given arguments. The Pure function may return multiple results as a tuple. Example:

`pure_call('succ', 99) => 100`

19.8 Gnuplot Interface

Octave has a comprehensive plotting interface based on Gnuplot. To make the plotting capabilities available in a convenient form in Pure, the distribution includes an additional gnuplotpure module which provides simple wrappers of the most important plotting functions. Please check gnuplotpure for details. For instance, here are a few simple plotting commands:

```octave
using gnuplot;
using namespace gnuplot;

sombrero(); // sample "sombrero" plot (3d)
popup(); // show the plot window
peaks 25; // another sample 3d plot
refresh(); // update the window
popdn(); // hide the plot window
print "plot.eps"; // print the plot to an encapsulated PostScript file
```

Note that most of the operations are in their own gnuplot namespace, so we used a using namespace declaration for convenience here. The following example does the “sombrero” plot again, but shows some of the explicit plotting commands and helper functions to generate the data:
using math;
let u = linspace (-8, 8, 41);
let x,y = meshgrid2 u;
let z = {sin r/r | r = {sqrt (x^2+y^2)+eps() | x,y = zip x y}};
mesh (u, u, z);
popup();

Note the commands that are needed to actually show the plot window and update its contents after doing each plot. Octave normally handles this automatically in its command loop, but since the embedded Octave interpreter doesn’t have an interactive command line, you’ll have to take care of this yourself when using this module.

Also note that there doesn’t seem to be a direct way to specify the default output terminal in the Octave gnuplot interface, so if you need to do this then you’ll have to set the GNUTERM environment variable as described in the gnuplot manual page.

### 19.9 Caveats and Notes

Directly embedding Octave in Pure programs is convenient because it allows easy exchange of data between Pure and Octave, and you can also call Octave functions directly from Pure and vice versa. However, it also comes at a cost. A default build of Octave pulls in quite a few dependencies of its own which might conflict with other modules loaded in a Pure script. Specifically, we have found that older Octave versions may give problems with third-party graphics libraries such as VTK, if used in the same program as Octave. (These seem to be fixed in the latest Octave and VTK versions, however.)
Chapter 20

Pure-Rational - Rational number library for the Pure programming language

Version 0.1, April 11, 2018

Rob Hubbard
Albert Graef <aggraef@gmail.com>
Jiri Spitz <jiri.spitz@bluetone.cz>

This package provides a Pure port of Q+Q, Rob Hubbard’s rational number library for the Q programming language. The port was done by Jiri Spitz. It contains rational.pure, a collection of utility functions for rational numbers, and rat_interval.pure, a module for doing interval arithmetic needed by rational.pure. These modules are designed to work with the math.pure module (part of the standard Pure library), which contains the definition of Pure’s rational type and implements the basic rational arithmetic.

This document is an edited version of Rob’s original Q+Q manual available from the Q website, slightly adjusted to account for the Pure specifics of the implementation. In particular, note that the operations provided by rational.pure and rat_interval.pure live in their own rational and interval namespaces, respectively, so if you want to get unqualified access to the symbols of these modules (as the examples in this manual assume) then you’ll have to import the modules as follows:

```
using rational, rat_interval;
using namespace rational, interval;
```

Also note that rational always pulls in the math module, so you don’t have to import the latter explicitly if you are using rational.

Another minor difference to the Q version of this module is that rational results always have Pure bigints as their numerators and denominators, hence the L suffix in the printed results.
Also, unary minus binds weaker in Pure than the rational division operator, so a negative rational number will be printed as, e.g., \((-1L)\%2L\), which looks a bit funny but is correct since Pure rationals always carry their sign in the numerator.

### 20.1 Copying

Copyright (c) 2006 - 2010 by Rob Hubbard.
Copyright (c) 2006 - 2010 by Albert Graef <aggraef@gmail.com>.
Copyright (c) 2010 by Jiri Spitz <jiri.spitz@bluetone.cz>.

Pure-rational is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

Pure-rational is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

### 20.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-rational-0.1.tar.gz.

Then run `make install` (as root) to install pure-rational in the Pure library directory. This requires GNU make, and of course you need to have Pure installed.

`make install` tries to guess your Pure installation directory. If it gets this wrong, you can install using `make install prefix=/usr` which sets the installation prefix. Please see the Makefile for details.

### 20.3 Introduction

#### 20.3.1 The Rational Module

This module provides additional operations on the rational number type provided by the `math.pure` module in the standard library. The module is compatible with Pure version 0.43 (onwards).

#### 20.3.2 The Files and the Default Prelude

The implementation of the rational type and associated utilities is distributed across various files.
math.pure and Other Files

The file `math.pure` defines the type, its constructors and ‘deconstructors’ and basic arithmetical and mathematical operators and functions. This is part of the standard Pure library. A few definitions associated with rationals are also defined in other standard library modules. In particular, the type tests are contained in `primitives.pure`.

It is also possible to create rational complex numbers (in addition to double complex numbers and integral or Gaussian complex numbers). That is, rationals play nicely with the complex number constructors provided in the `math.pure` module. This is discussed further in `Rational Complex Numbers`.

rational.pure

Additional ‘rational utilities’, not included in the `math.pure` module, are defined in `rational.pure`. The functions include further arithmetical and mathematical operators and functions, continued fraction support, approximation routines and string formatting and evaluation.

The rational utilities include some ‘rational complex number’ functions.

rat_interval.pure

Amongst the rational utilities are some functions that return a rational interval. The file `rat_interval.pure` is a partial implementation of interval arithmetic. Intervals are discussed further in `Intervals`.

20.3.3 Notation

Throughout this document, the parameters `q, q0, q1, ...` usually denote rationals (`∈ Q`), parameters `z, ...` usually denote integers (`∈ Z`), `r, ...` usually denote real numbers (`∈ R`), `c, ...` usually denote complex numbers (`∈ C`), `n, ...` usually denote parameters of any numeric type, `v, ...` usually denote parameters of any interval type, and `x, ...` usually denote parameters of any type.

The reals are not just the doubles, but include rationals and integers. The term ‘rational’ usually refers to a rational number `∈ Q ⊃ Z`, or an expression of type rational or integer.

20.4 The Rational Type

20.4.1 Constructors

Rationals are constructed with the `%` exact division operator, and other kinds of numbers can be converted to rationals with the `rational` function. These are both defined in `math.pure`.

`n1 % n2`

is the exact division operator, which may be used as a constructor (for integers `n1` and `n2`). This is described in `More on Division`.

20.3.3 Notation
rational $x$
converts the given number $x$ to a rational.

**Example 1** Constructing a fraction:

```plaintext
> 44%14;
22L%7L
```

**Example 2** Converting from an integer:

```plaintext
> rational 3;
3L%1L
```

### 20.4.2 ‘Deconstructors’

A rational number is in simplest form if the numerator and denominator are coprime (i.e. do not have a factor in common) and the denominator is positive (and, specifically, non-zero). Sometimes the term ‘irreducible’ is used for a rational in simplest form. This is a property of the representation of the rational number and not of the number itself.

**num** $q$

given a rational or integer $q$, returns the ‘(signed) simplest numerator’, i.e. the numerator of the normalised form of $q$.

**den** $q$

given a rational or integer $q$, returns the ‘(positive) simplest denominator’, i.e. the denominator of the normalised form of $q$.

**rational::num_den** $q$

given a rational or integer $q$, returns a pair $(n, d)$ containing the (signed) simplest numerator $n$ and the (positive) simplest denominator $d$. This is the inverse (up to equivalence) of rational as defined on integer pairs (see **Constructors**).

**Example 3** Using **num_den** to obtain a representation in simplest form:

```plaintext
> let q = (44%(-14));
> num q;
-22L
> den q;
7L
> num_den q;
-22L,7L
> num_den 3;
3L,1L
> num_den (-3);
-3L,1L
```

Together, **num** and **den** are a pair of ‘decomposition’ operators, and **num_den** is also a decomposition operator. There are others (see **Decomposition**). The integer and fraction function (see **Integer and Fraction Parts**) may be used in conjunction with **num_den_gauss** to decompose a rational into integer, numerator and denominator parts.
20.4.3 Type and Value Tests

The functions `rationalp` and `ratvalp` and other rational variants are new for rationals and the standard functions `exactp` and `inexactp` are extended for rationals.

A value is 'exact', or of an exact type, if it is of a type that is able to represent the values returned by arithmetical operations exactly; in a sense, it is ‘closed’ under arithmetical operations. Otherwise, a value is ‘inexact’. Inexact types are able to store some values only approximately.

The doubles are not an exact type. The results of some operations on some values that are stored exactly, can’t be stored exactly. (Furthermore, doubles are intended to represent real numbers; no irrational number ($\in \mathbb{R} \setminus \mathbb{Q}$) can be stored exactly as a double; even some rational ($\in \mathbb{Q}$) numbers are not stored exactly.)

The rationals are an exact type. All rational numbers (subject to available resources, of course) are stored exactly. The results of the arithmetical operations on rationals are rationals represented exactly. Beware that the standard `intvalp` and `ratvalp` may return 1 even if the value is of double type. However, these functions may be combined with `exactp`.

`exactp x` returns whether x has an exact value.

`inexactp x` returns whether x has an inexact value.

`rationalp x` returns whether x is of rational type.

`ratvalp x` returns whether x has a rational value.

Example 4 Rational value tests:

```scheme
> let l = [9, 9%1, 9%2, 4.5, sqrt 2, 1+i, inf, nan];
> map exactp l;
[1,1,1,0,0,1,0,0]
> map inexactp l;
[0,0,0,1,1,0,1,1]
> map rationalp l;
[0,1,1,0,0,0,0,0]
> map ratvalp l;
[1,1,1,1,0,0,0,0]
> map (\x -> (exactp x && ratvalp x)) l; // "has exact rational value"
[1,1,1,0,0,0,0,0]
> map intvalp l; // for comparison
[1,1,0,0,0,0,0,0]
> map (\x -> (exactp x && intvalp x)) l; // "has exact integer value"
[1,1,0,0,0,0,0,0]
```

See Rational Complex Numbers for details about rational complex numbers, and Rational Complex Type and Value Tests for details of their type and value tests.
20.5 Arithmetic

20.5.1 Operators

The standard arithmetic operators (+), (−) and (*) are overloaded to have at least one rational operand. If both operands are rational then the result is rational. If one operand is integer, then the result is rational. If one operand is double, then the result is double.

The operators (/) and (%) are overloaded for division on at least one rational operand. The value returned by (/) is always inexact (in the sense of Type and Value Tests). The value returned by (%) is exact (if it exists).

The standard function pow is overloaded to have a rational left operand. If pow is passed integer operands where the right operand is negative, then a rational is returned. The right operand should be an integer; negative values are permitted (because q^{−z} = 1/q^z). It is not overloaded to also have a rational right operand because such values are not generally rational (e.g. q^{1/n} = n√q).

The standard arithmetic operator (^) is also overloaded, but produces a double value (as always).

Example 5 Arithmetic:

```plaintext
> 5%7 + 2%3;
29L%21L
> str_mixed ans;
"1L+8L/21L"
> 1 + 2%3;
5L%3L
> ans + 1.0;
2.66666666666667
> 3%8 - 1%3;
1L%24L
> (11%10) ^ 3;
1.331
> pow (11%10) 3;
1331L%1000L
> pow 3 5;
243L
> pow 3 (-5);
1L%243L
```

(See the function str_mixed.)

Beware that (/) on integers will not produce a rational result.

Example 6 Division:

```plaintext
> 44/14;
3.14285714285714
> 44%14;
22L%7L
> str_mixed ans;
"3L+1L/7L"
```
There is a rational-aware divide operator on the numeric types:

\[ n_1 \div n_2 \]

returns the quotient (\( \in \mathbb{Q} \)) of \( n_1 \) and \( n_2 \). If \( n_1 \) and \( n_2 \) are rational or integer then the result is rational. This operator has the precedence of division (\( / \)).

**Example 7** Using \( \% \) like a constructor:

```cpp
> 44 \% 14;
22L%7L
> 2 + 3\%8;  // "2 3/8"
19L%8L
> str_mixed ans;
"2L+3L/8L"
```

(See the function `str_mixed`.)

```cpp
rational::reciprocal n
returns the reciprocal of \( n \): \( 1/n \).
```

**Example 8** Reciprocal:

```cpp
> reciprocal (22\%7);
7L%22L
```

The following division functions are parameterised by a rounding mode `roundfun`. The available rounding modes are described in Rounding to Integer.

```cpp
rational::divide roundfun n d
for rationals \( n \) and \( d \) returns a pair \((q, r)\) of ‘quotient’ and ‘remainder’ where \( q \) is an integer and \( r \) is a rational such that \(|r| < |d|\) (or better) and \( n = q \cdot d + r \). Further conditions may hold, depending on the chosen rounding mode `roundfun` (see Rounding to Integer). If `roundfun` = `floor` then \( 0 \leq r < d \). If `roundfun` = `ceil` then \(-d < r \leq 0 \). If `roundfun` = `trunc` then \(|r| < |d|\) and \( \text{sgn} r \in \{0, \text{sgn} d\} \). If `roundfun` = `round`, `roundfun` = `round_zero_bias` or `roundfun` = `round_unbiased` then \(|r| \leq d/2 \).

```cpp
rational::quotient roundfun nN d
returns just the quotient as produced by `divide` roundfun n d.
```

```cpp
rational::modulus roundfun n d
returns just the remainder as produced by `divide` roundfun n d.
```

\[ q_1 \div q_2 \]

(overload of the built-in `div`) \( q_1 \) and \( q_2 \) may be rational or integer. Returns an integer.

\[ q_1 \mod q_2 \]

(overload of the built-in `mod`) \( q_1 \) and \( q_2 \) may be rational or integer. Returns a rational. If \( q = q_1 \div q_2 \) and \( r = q_1 \mod q_2 \) then \( q_1 = q \cdot q_2 + q \), \( q \in \mathbb{Z} \), \(|r| < |q_2|\) and \( \text{sgn} r \in \{0, \text{sgn} q_2\} \).
20.5.3 Relations — Equality and Inequality Tests

The standard arithmetic operators (==), (==), (<), (<=), (>), (>=) are overloaded to have at least one rational operand. The other operand may be rational, integer or double.

Example 9 Inequality:

```
> 3%8 < 1%3;
0
```

20.5.4 Comparison Function

```
second::cmp n1 n2
```

is the ‘comparison’ (or ‘compare’) function, and returns sgn (n1 - n2); that is, it returns −1 if n1 < n2, 0 if n1 = n2, and +1 if n1 > n2.

Example 10 Compare:

```
> cmp (3%8) (1%3);
1
```

20.6 Mathematical Functions

Most mathematical functions, including the elementary functions (sin, sin^{-1}, sinh, sinh^{-1}, cos, ... , exp, ln, ... ), are not closed on the set of rational numbers. That is, most mathematical functions do not yield a rational number in general when applied to a rational number. Therefore the elementary functions are not defined for rationals. To apply these functions, first apply a cast to double, or compose the function with a cast.

20.6.1 Absolute Value and Sign

The standard abs and sgn functions are overloaded for rationals.

```
abs q
```

returns absolute value, or magnitude, |q| of q; abs q = |q| = q × sgn q (see below).

```
sgn q
```

returns the sign of q as an integer; returns −1 if q < 0, 0 if q = 0, +1 if q > 0.

Together, these functions satisfy the property ∀q • (sgn q) * (abs q) = q (i.e. ∀q • (sgn q) * |q| = q). Thus these provide a pair of ‘decomposition’ operators; there are others (see Decomposition).

20.6.2 Greatest Common Divisor (GCD) and Least Common Multiple (LCM)

The standard functions gcd and lcm are overloaded for rationals, and mixtures of integer and rational.

```
gcd n1 n2
```

The GCD is also known as the Highest Common Factor (HCF). The GCD of rationals q1 and q2 is the largest (therefore positive) rational f such that f divides into both q1
and q2 exactly, i.e. an integral number of times. This is not defined for n1 and n2 both zero. For integral q1 and q2, this definition coincides with the usual definition of GCD for integers.

**Example 11** With two rationals:

```plaintext
> let a = 7%12;
> let b = 21%32;
> let f = gcd a b;
> f;
7L%96L
> a % f;
8L%1L
> b % f;
9L%1L
```

**Example 12** With a rational and an integer:

```plaintext
> let f = gcd (6%5) 4;
> f;
2L%5L
> (6%5) % f;
3L%1L
> 4 % f;
10L%1L
```

**Example 13** With integral rationals and with integers:

```plaintext
> gcd (rational 18) (rational 24);
6L%1L
> gcd 18 24;
6
```

**Example 14** The behaviour with negative numbers:

```plaintext
> gcd (rational (-18)) (rational 24);
6L%1L
> gcd (rational 18) (rational (-24));
6L%1L
> gcd (rational (-18)) (rational (-24));
6L%1L
```

**lcm** n1 n2

The LCM of rationals q1 and q2 is the smallest positive rational m such that both q1 and q2 divide m exactly. This is not defined for n1 and n2 both zero. For integral q1 and q2, this definition coincides with the usual definition of LCM for integers.

**Example 15** With two rationals:

```plaintext
> let a = 7%12;
> let bB = 21%32;
> let m = lcm a b;
> m;
21L%4L
```
Example 16 With a rational and an integer:

> let m = lcm (6%5) 4;
> m;
12L%1L
> m % (6%5);
10L%1L

Example 17 The behaviour with negative numbers:

> lcm (rational (-18)) (rational 24);
72L%1L
> lcm (rational 18) (rational (-24));
72L%1L
> lcm (rational (-18)) (rational (-24));
72L%1L

Together, the GCD and LCM have the following property when applied to two numbers:
\[(\text{gcd } q1 \ q2) \times (\text{lcm } q1 \ q2) = \lvert q1 \times q2 \rvert.\]

20.6.3 Extrema (Minima and Maxima)

The standard min and max functions work with rational values.

Example 18 Maximum:

> max (3%8) (1%3);
3L%8L

20.7 Special Rational Functions

20.7.1 Complexity

The ‘complexity’ (or ‘complicatedness’) of a rational is a measure of the greatness of its simplest (positive) denominator.

The complexity of a number is not itself made available, but various functions and operators are provided to allow complexities to be compared. Generally, it does not make sense to operate directly on complexity values.

The complexity functions in this section may be applied to integers (the least complex), rationals, or reals (doubles; the most complex).

Functions concerning ‘complexity’ are named with ‘cplx’, whereas functions concerning ‘complex numbers’ (see Rational Complex Numbers) are named with ‘comp’.
Complexity Relations

\texttt{n1 rational::eq\_cplx n2}

“[is] equally complex [to]” — returns 1 if \( n1 \) and \( n2 \) are equally complex; returns 0 otherwise. Equal complexity is not the same a equality; \( n1 \) and \( n2 \) are equally complex if their simplest denominators are equal. Equal complexity forms an equivalence relation on rationals.

\textbf{Example 19} Complexity equality test:

\begin{verbatim}
> (1%3) eq\_cplx (100%3); 1
> (1%4) eq\_cplx (1%5); 0
> (3%3) eq\_cplx (1%3); // LHS is not in simplest form 0
\end{verbatim}

\texttt{n1 rational::not\_eq\_cplx n2}

“not equally complex” — returns 0 if \( n1 \) and \( n2 \) are equally complex; returns 1 otherwise.

\texttt{n1 rational::less\_cplx n2}

“[is] less complex [than]” (or “simpler”) — returns 1 if \( n1 \) is strictly less complex than \( n2 \); returns 0 otherwise. This forms a partial strict ordering on rationals.

\textbf{Example 20} Complexity inequality test:

\begin{verbatim}
> (1%3) less\_cplx (100%3); 0
> (1%4) less\_cplx (1%5); 1
> (3%3) less\_cplx (1%3); // LHS is not in simplest form 1
\end{verbatim}

\texttt{n1 rational::less\_eq\_cplx n2}

“less or equally complex” (or “not more complex”) — returns 1 if \( n1 \) is less complex than or equally complex to \( n2 \); returns 0 otherwise. This forms a partial non-strict ordering on rationals.

\texttt{n1 rational::more\_cplx n2}

“[is] more complex [than]” — returns 1 if \( n1 \) is strictly more complex than \( n2 \); returns 0 otherwise. This forms a partial strict ordering on rationals.

\texttt{n1 rational::more\_eq\_cplx n2}

“more or equally complex” (or “not less complex”) — returns 1 if \( n1 \) is more complex than or equally complex to \( n2 \); returns 0 otherwise. This forms a partial non-strict ordering on rationals.

\textbf{Complexity Comparison Function}

\texttt{rational::cmp\_complexity n1 n2}

is the ‘complexity comparison’ function, and returns the sign of the difference in com-
plexity; that is, it returns $-1$ if $n_1$ is less complex than $n_2$, $0$ if $n_1$ and $n_2$ are equally complex (but not necessarily equal), and $+1$ if $n_1$ is more complex than $n_2$.

**Example 21** Complexity comparison:

```cpp
cmp_complexity (1%3) (100%3);
0
```

```cpp
cmp_complexity (1%4) (1%5);
-1
```

```cpp
cmp_complexity (3%3) (1%3); // LHS is not in simplest form
-1
```

**Complexity Extrema**

```cpp
rational::least_cplx n1 n2
```

returns the least complex of $n_1$ and $n_2$; if they’re equally complex, $n_1$ is returned.

**Example 22** Complexity selection:

```cpp
least_cplx (100%3) (1%3);
100L%3L
```

```cpp
least_cplx (1%5) (1%4);
1L%4L
```

```cpp
least_cplx (1%3) (3%3); // second argument not in simplest form
1L%1L
```

```cpp
rational::most_cplx n1 n2
```

returns the most complex of $n_1$ and $n_2$; if they’re equally complex, $n_1$ is returned.

**Other Complexity Functions**

```cpp
rational::complexity_rel n1 op n2
```

returns “complexity-of $n_1$” compared by operator $op$ to the “complexity-of $n_2$”. This is equivalent to prefix complexity $rel$ $op$ $n_1$ $n_2$ (below), but is the more readable form.

**Example 23** Complexity relations:

```cpp
complexity_rel (1%3) (==) (100%3);
1
```

```cpp
complexity_rel (1%4) (<=) (1%5);
1
```

```cpp
complexity_rel (1%4) (>) (1%5);
0
```

```cpp
rational::complexity_rel op n1 n2
```

returns the same as complexity_rel $n_1$ $op$ $n_2$, but this form is more convenient for currying.

**20.7.2 Mediants and Farey Sequences**

```cpp
rational::mediant q1 q2
```

returns the canonical mediant of the rationals $q_1$ and $q_2$, a form of (nonarithmetic)
average on rationals. The mediant of the representations \( \frac{n_1}{d_1} = q_1 \) and \( \frac{n_2}{d_2} = q_2 \), where \( d_1 \) and \( d_2 \) must be positive, is defined as \( \frac{n_1 + n_2}{d_1 + d_2} \). A mediant of the rationals \( q_1 \) and \( q_2 \) is a mediant of some representation of each of \( q_1 \) and \( q_2 \). That is, the mediant is dependent upon the representations and therefore is not well-defined as a function on pairs of rationals. The canonical mediant always assumes the simplest representation, and therefore is well-defined as a function on pairs of rationals.

By the phrase “the mediant” (as opposed to just “a mediant”) we always mean “the canonical mediant”.

If \( q_1 < q_2 \), then any mediant \( q \) is always such that \( q_1 < q < q_2 \).

The (canonical) mediant has some special properties. If \( q_1 \) and \( q_2 \) are integers, then the mediant is the arithmetic mean. If \( q_1 \) and \( q_2 \) are unit fractions (reciprocals of integers), then the mediant is the harmonic mean. The mediant of \( q \) and \( 1/q \) is \( \pm 1 \), (which happens to be a geometric mean with the correct sign, although this is a somewhat uninteresting and degenerate case).

**Example 24** Mediants:

```plaintext
> median (1%4) (3%10);
2%7L
> median 3 7; // both integers
5%11L
> median 3 8; // both integers again
11%2L
> median (1%3) (1%7); // both unit fractions
1L%5L
> median (1%3) (1%8); // both unit fractions again
2L%11L
> median (-10) (-1%10);
(-1L)%1L
```

`rational::farey k`

for an integer \( k \), `farey` returns the ordered list containing the order-\( k \) Farey sequence, which is the ordered list of all rational numbers between 0 and 1 inclusive with (simplest) denominator at most \( k \).

**Example 25** A Farey sequence:

```plaintext
> map str_mixed (farey 6);
["0L","1L/6L","1L/5L","1L/4L","1L/3L","2L/5L","1L/2L","3L/5L","2L/3L","3L/4L","4L/5L","5L/6L","1L"]
```

(See the function `str_mixed`.)

Farey sequences and mediants are closely related. Three rationals \( q_1 < q_2 < q_3 \) are consecutive members of a Farey sequence if and only if \( q_2 \) is the mediant of \( q_1 \) and \( q_3 \). If rationals \( q_1 = n_1/d_1 < q_2 = n_2/d_2 \) are consecutive members of a Farey sequence, then \( n_2d_1 − n_1d_2 = 1 \).
20.7.3 Rational Type Simplification

rational::rat_simplify q

returns q with rationals simplified to integers, if possible.

Example 26 Rational type simplification:

> let l = [9, 9%1, 9%2, 4.5, 9%1+i, 9%2+i]; l;
[9,9L%1L,9L%2L,4.5,9L%1L+:1,9L%2L+:1]
> map rat_simplify l;
[9,9,9L%2L,4.5,9+:1,9L%2L+:1]

See Rational Complex Numbers for details about rational complex numbers, and Rational Complex Type Simplification for details of their type simplification.

20.8 Q -> Z — Rounding

20.8.1 Rounding to Integer

Some of these are new functions, and some are overloads of standard functions. The behaviour of the overloads is consistent with that of the standard functions.

floor q

(overload of standard function) returns q rounded downwards, i.e. towards \(-1\), to an integer, usually denoted \(\lfloor q \rfloor\).

ceil q

(overload of standard function) returns q rounded upwards, i.e. towards \(+1\), to an integer, usually denoted \(\lceil q \rceil\).

trunc q

(overload of standard function) returns q truncated, i.e. rounded towards 0, to an integer.

round q

(overload of standard function) returns q ‘rounded off’, i.e. rounded to the nearest integer, with ‘half-integers’ (values that are an integer plus a half) rounded away from zero.

rational::round_zero_bias q

(new function) returns q ‘rounded off’, i.e. rounded to the nearest integer, but with ‘half-integers’ rounded towards zero.

rational::round_unbiased q

(new function) returns q rounded to the nearest integer, with ‘half-integers’ rounded to the nearest even integer.

Example 27 Illustration of the different rounding modes:

> let l = iterwhile (<= 3) (+%2) (- rational 3);
> map double l; // (just to show the values in a familiar format)
[-3.0,-2.5,-2.0,-1.5,-1.0,-0.5,0.0,0.5,1.0,1.5,2.0,2.5,3.0]
Pure Language and Library Documentation, Release 0.68

> map floor l;
[-3L, -3L, -2L, -2L, -1L, -1L, 0L, 1L, 1L, 2L, 2L, 3L]
> map ceil l;
[-3L, -2L, -2L, -1L, -1L, 0L, 0L, 1L, 1L, 2L, 2L, 3L]
> map trunc l;
[-3L, -2L, -2L, -1L, -1L, 0L, 0L, 0L, 1L, 1L, 2L, 2L, 3L]
> map round l;
[-3L, -2L, -2L, -1L, -1L, 0L, 0L, 0L, 1L, 2L, 2L, 3L]
> map round_zero_bias l;
[-3L, -2L, -2L, -1L, -1L, 0L, 0L, 0L, 1L, 1L, 2L, 2L, 3L]
> map round_unbiased l;
[-3L, -2L, -2L, -1L, -1L, 0L, 0L, 0L, 1L, 2L, 2L, 3L]

(See the function double.)

20.8.2 Integer and Fraction Parts

rational::integer_and_fraction roundfun q
returns a pair (z, f) where z is the ‘integer part’ as an integer, f is the ‘fraction part’ as a rational, where the rounding operations are performed using rounding mode roundfun (see Rounding to Integer).

Example 28 Integer and fraction parts with the different rounding modes:

> let nc = -22%7;
> integer_and_fraction floor nc;
-4L, 6L%7L
> integer_and_fraction trunc nc;
-3L, (-1L)%7L
> integer_and_fraction round nc;
-3L, (-1L)%7L

It is always the case that z and f have the property that q = z + f. However, the remaining properties depend upon the choice of roundfun; there are others (see Decomposition). If roundfun = floor then 0 ≤ f < 1. If roundfun = ceil then −1 < f ≤ 0. If roundfun = trunc then |f| < 1 and sgn f ∈ {0, sgn q}. If roundfun = round, roundfun = round_zero_bias or roundfun = round_unbiased then |f| ≤ 1/2.

rational::fraction roundfun q
returns just the ‘fraction part’ as a rational, where the rounding operations are performed using roundfun. The corresponding function ‘integer’ is not provided, as integer roundfun q would be just roundfun q. The integer and fraction function (probably with trunc or floor rounding mode) may be used in conjunction with num_den (see ‘Deconstructors’) to decompose a rational into integer, numerator and denominator parts.

int q
overloads the built-in int and returns the ‘integer part’ of q consistent with the built-in.

frac q
overloads the built-in frac and returns the ‘fraction part’ of q consistent with the built-
Example 29 Standard integer and fraction parts:

```plaintext
> let nc = -22%7;
> int nc;
-3
> frac nc;
(-1L)%7L
```

### 20.9 Rounding to Multiples

**rational::round_to_multiple** roundfun multOf q
returns q rounded to an integer multiple of a non-zero value multOf, using roundfun as the rounding mode (see Rounding to Integer). Note that it is the multiple that is rounded in the prescribed way, and not the final result, which may make a difference in the case that multOf is negative. If that is not the desired behaviour, pass this function the absolute value of multOf rather than multOf. Similar comments apply to the following functions.

**rational::floor_multiple** multOf q
returns q rounded to a downwards integer multiple of multOf.

**rational::ceil_multiple** multOf q
returns q rounded to an upwards integer multiple of multOf.

**rational::trunc_multiple** multOf q
returns q rounded towards zero to an integer multiple of multOf.

**rational::round_multiple** multOf q
returns q rounded towards the nearest integer multiple of multOf, with half-integer multiples rounded away from 0.

**rational::round_multiple_zero_bias** multOf q
returns q rounded towards the nearest integer multiple of multOf, with half-integer multiples rounded towards 0.

**rational::round_multiple_unbiased** multOf q
returns q rounded towards the nearest integer multiple of multOf, with half-integer multiples rounded to an even multiple.

Example 30 Round to multiple:

```plaintext
> let l = [34.9, 35, 35%1, 35.0, 35.1];
> map double l; // (just to show the values in a familiar format)
[34.9,35.0,35.0,35.0,35.1]
> map (floor_multiple 10) l;
[30.0,30L,30L,30.0,30.0]
> map (ceil_multiple 10) l;
[40.0,40L,40L,40.0,40.0]
> map (trunc_multiple 10) l;
[30.0,30L,30L,30.0,30.0]
```
> map (round_multiple 10) l;  
[30.0,40L,40L,40.0,40.0]  
> map (round_multiple_zero_bias 10) l;  
[30.0,30L,30L,30.0,40.0]  
> map (round_multiple_unbiased 10) l;  
[30.0,40L,40L,40.0,40.0]  

(See the function double.)

The round multiple functions may be used to find a fixed denominator approximation of a number. (The simplest denominator may actually be a proper factor of the chosen value.) To approximate for a bounded (rather than particular) denominator, use rational approx max den instead (see Best Approximation with Bounded Denominator).

**Example 31** Finding the nearest \( q = n/d \) value to \( 1/e \approx 0.368 \) where \( d = 1000 \) (actually, where \( d \mid 1000 \)):

```haskell
> let co_E = exp (-1);
co_E;
0.367879441171442
> round_multiple (1%1000) (rational co_E);
46L%125L
> 1000 * ans;
368L%1L
```

**Example 32** Finding the nearest \( q = n/d \) value to \( 1/\phi \approx 0.618 \) where \( d = 3^5 = 243 \) (actually, where \( d \mid 243 \)):

```haskell
> let co_Phi = (sqrt 5 - 1) / 2;
> round_multiple (1%243) (rational co_Phi);
50L%81L
```

Other methods for obtaining a rational approximation of a number are described in R -> Q — Approximation.

### 20.10 Q -> R — Conversion / Casting

double q  
(overload of built-in) returns a double having a value as close as possible to q. (Overflow, underflow and loss of accuracy are potential problems. rationals that are too absolutely large or too absolutely small may overflow or underflow; some rationals can not be represented exactly as a double.)

### 20.11 R -> Q — Approximation

This section describes functions that approximate a number (usually a double) by a rational. See Rounding to Multiples for approximation of a number by a rational with a fixed denominator. See Numeral String -> Q — Approximation for approximation by a rational of a string representation of a real number.
20.11.1 Intervals

Some of the approximation functions return an interval. The file rat..interval..pure is a basic implementation of interval arithmetic, and is not included in the default prelude. It is not intended to provide a complete implementation of interval arithmetic. The notions of ‘open’ and ‘closed’ intervals are not distinguished. Infinite and half-infinite intervals are not specifically provided. Some operations and functions may be missing. The most likely functions to be used are simply the ‘deconstructors’; see Interval Constructors and ‘Deconstructors’.

Interval Constructors and ‘Deconstructors’

Intervals are constructed with the function interval.

\[
\text{interval} ::= \text{interval} (n1, n2) \\
\text{given a pair of numbers (z1 <= z2), this returns the interval z1..z2. This is the inverse of lo..up.}
\]

**Example 33** Constructing an interval:

\[
> \text{let } v = \text{interval}\ (3, 8); \\
> v; \\
\text{interval::Ivl 3 8}
\]

\[
\text{interval::lower } v \\
\text{returns the infimum (roughly, minimum) of } v.
\]

\[
\text{interval::upper } v \\
\text{returns the supremum (roughly, maximum) of } v.
\]

\[
\text{interval::lo..up } v \\
\text{returns a pair (l, u) containing the lower l and upper u extrema of the interval } v. \text{ This is the inverse of interval as defined on number pairs.}
\]

**Example 34** Deconstructing an interval:

\[
> \text{lower } v; \\
3 \\
> \text{upper } v; \\
8 \\
> \text{lo..up } v; \\
3, 8
\]

Interval Type Tests

\[
\text{exactp } v \\
\text{returns whether an interval } v \text{ has exact extrema.}
\]

\[
\text{inexactp } v \\
\text{returns whether an interval } v \text{ has an inexact extremum.}
\]

\[
\text{interval::intervalp } x \\
\text{returns whether } x \text{ is of type interval.}
\]
interval::\texttt{interval\_valp} \texttt{x}
returns whether \texttt{x} has an interval value.

interval::\texttt{ratinterval\_valp} \texttt{x}
returns whether \texttt{x} has an interval value with rational extrema.

interval::\texttt{intinterval\_valp} \texttt{x}
returns whether \texttt{x} has an interval value with integral extrema.

Example 35 Interval value tests:

\begin{verbatim}
> let l = [interval(0,1), interval(0,1%1), interval(0,3%2), interval(0,1.5)];
> map exactp l;
[1,1,1,1]
> map inexactp l;
[0,0,0,1]
> map intervalp l;
[1,1,1,1]
> map interval\_valp l;
[1,1,1,1]
> map ratinterval\_valp l;
[1,1,1,1]
> map intinterval\_valp l;
[1,1,0,0]
\end{verbatim}

Interval Arithmetic Operators and Relations

The standard arithmetic operators (+), (−), (•), (/) and (%) are overloaded for intervals. The divide operators (/) and (%) do not produce a result if the right operand is an interval containing 0. Example 36 Some intervals:

\begin{verbatim}
> let a = interval (11, 19);
> let b = interval (16, 24);
> let c = interval (21, 29);
> let d = interval (23, 27);
\end{verbatim}

Example 37 Interval arithmetic:

\begin{verbatim}
> let p = interval (0, 1);
> let s = interval (-1, 1);
> a + b;
interval::Ivl 27 43
> a - b;
interval::Ivl (-13) 3
> a * b;
interval::Ivl 176 456
> p * 2;
interval::Ivl 0 2
> (-2) * p;
interval::Ivl (-2) 0
> -c;
interval::Ivl (-29) (-21)
> s * a;
\end{verbatim}
interval::Ivl (-19) 19
> a % 2;
interval::Ivl (11L\%2L) (19L\%2L)
> a / 2;
interval::Ivl 5.5 9.5
> reciprocal a;
interval::Ivl (1L\%19L) (1L\%11L)
> 2 % a;
interval::Ivl (2L\%19L) (2L\%11L)
> a % b;
interval::Ivl (11L\%24L) (19L\%16L)
> a % a; // notice that the intervals are mutually independent here
interval::Ivl (11L\%19L) (19L\%11L)

There are also some relations defined for intervals. The standard relations (==) and (\!\!=) are overloaded.

However, rather than overloading (<), (\leq), (>, (\geq), which could be used for either ordering or containment with some ambiguity, the module defines (before), (within), and so on. ‘Strictness’ refers to the properties at the end-points.

v1 interval::before v2
    returns whether v1 is entirely before v2.

v1 interval::strictly_before v2
    returns whether v1 is strictly entirely before v2.

v1 interval::after v2
    returns whether v1 is entirely after v2.

v1 interval::strictly_after v2
    returns whether v1 is strictly entirely after v2.

v1 interval::within v2
    returns whether v1 is entirely within v2; i.e. whether v1 is subinterval of v2.

v1 interval::strictly_within v2
    returns whether v1 is strictly entirely within v2; i.e. whether v1 is proper subinterval of v2.

v1 interval::without v2
    returns whether v1 entirely contains v2; i.e. whether v1 is superinterval of v2. 'Without' is used in the sense of outside or around.

v1 interval::strictly_without v2
    returns whether v1 strictly entirely contains v2; i.e. whether v1 is proper superinterval of v2.

v1 interval::disjoint v2
    returns whether v1 and v2 are entirely disjoint.

v1 interval::strictly_disjoint v2
    returns whether v1 and v2 are entirely strictly disjoint.
Example 38 Interval relations:

```plaintext
> a == b; 0
> a == a; 1
> a before b; 0
> a before c; 1
> c before a; 0
> a disjoint b; 0
> c disjoint a; 1
> a within b; 0
> a within c; 0
> d within c; 1
> c within d; 0
> a strictly_within a; 0
> a within a; 1
```

(The symbols a through d were defined in Example 36.)

These may also be used with a simple (real) value, and in particular to test membership.

Example 39 Membership:

```plaintext
> 10 within a; 0
> 11 within a; 1
> 11.0 within a; 1
> 12 within a; 1
> 12.0 within a; 1
> 10 strictly_within a; 0
> 11 strictly_within a; 0
> (11%1) strictly_within a; 0
> 12 strictly_within a; 1
> (12%1) strictly_within a;
```
Interval Maths

Some standard functions are overloaded for intervals; some new functions are provided.

abs \( v \)

returns the interval representing the range of \( (x) \) as \( x \) varies over \( v \).

**Example 40** Absolute interval:

\[
\text{abs (interval (1, 5));} \\
\text{interval::Ivl 1 5} \\
\text{abs (interval (-1, 5));} \\
\text{interval::Ivl 0 5} \\
\text{abs (interval (-5, -1));} \\
\text{interval::Ivl 1 5}
\]

\( \text{sgn} \ v \)

returns the interval representing the range of \( \text{sgn}(x) \) as \( x \) varies over \( v \).

**Example 41** Absolute interval:

\[
\text{#d;} \\
4
\]

(The symbol d was defined in Example 36.)

### 20.11.2 Least Complex Approximation within Epsilon

\( \text{rational::rational\_approx\_epsilon} \epsilon \) \( r \)

Find the least complex (see Complexity Extrema) rational approximation to \( r \) (usually a double) that is \( \epsilon \)-close. That is find the \( q \) with the smallest possible denominator such that such that \( |q - r| \leq \epsilon. (\epsilon > 0.) \)

**Example 42** Rational approximation to \( \pi \approx 3.142 \approx 22/7 \):

\[
> \text{rational\_approx\_epsilon .01 pi;} \\
22L\%7L \\
> \text{abs (ans - pi);} \\
0.00126448926734968
\]

**Example 43** The golden ratio \( \phi = (1 + \sqrt{5}) / 2 \approx 1.618 \):

\[
> \text{let phi = (1 + sqrt 5) / 2;} \\
> \text{rational\_approx\_epsilon .001 phi;} \\
55L\%34L \\
> \text{abs (ans - phi);} \\
0.000386929926365465
\]
rational::rational_approxs_epsilon \epsilon r

Produce a list of ever better rational approximations to r (usually a double) that is eventually \epsilon-close. (\epsilon > 0.)

Example 44 Rational approximations to \pi:

> rational_approxs_epsilon .0001 pi;
[3L%1L, 25L%8L, 47L%15L, 69L%22L, 91L%29L, 113L%36L, 135L%43L, 157L%50L, 179L%57L, 201L%64L, 223L%71L, 245L%78L, 267L%85L, 289L%92L, 311L%99L, 333L%106L]

Example 45 Rational approximations to the golden ratio \phi; these approximations are always reverse consecutive Fibonacci numbers (from f1: 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, ...):

> rational_approxs_epsilon .0001 phi;
[1L%1L, 3L%2L, 8L%5L, 21L%13L, 55L%34L, 144L%89L]

(The symbol phi was defined in Example 43.)

rational::rational_interval_epsilon \epsilon r

Find the least complex (see Complexity Extrema) rational interval containing r (usually a double) that is \epsilon-small. That is find the least complex (see Complexity Extrema) q1 \leq q2 such that r \in [q1, q2] and q2 - q1 \leq \epsilon. (\epsilon > 0.)

Example 46 Rational interval surrounding \pi:

> let i_Pi = rational_interval_epsilon .01 pi;
> i_Pi;
interval::Ivl (47L%15L) (22L%7L)
> double (lower i_Pi); pi;
3.13333333333333
3.14159265358979
3.14285714285714

(The functions lower and upper are described in Interval Constructors and ‘Deconstructors’.)

Example 47 Rational interval surrounding the golden ratio \phi:

> rational_interval_epsilon .001 phi;
interval::Ivl (55L%34L) (89L%55L)
> #ans;
1L%1870L

(The symbol phi was defined in Example 43. The function # is described in Interval Maths.)

20.11.3 Best Approximation with Bounded Denominator

rational::rational_approx_max_den maxDen r

Find the closest rational approximation to r (usually a double) that has a denominator no greater than maxDen. (maxDen > 0.)

Example 48 Rational approximation to \pi:

> rational_approx_max_den 10 pi;
22L%7L
Example 49  Rational approximation to the golden ratio $\phi$:

> rational.approx_max_den 1000 phi;
1597L%987L

(The symbol phi was defined in Example 43.)

Example 50  Rational approximations to $\pi$:

> rational.approx_max_den 100 pi;
[3L%1L, 25L%8L, 47L%15L, 69L%22L, 91L%29L, 113L%36L, 135L%43L, 157L%50L, 179L%57L,
201L%64L, 223L%71L, 245L%78L, 267L%85L, 289L%92L, 311L%99L]

Example 51  Rational approximations to the golden ratio $\phi$:

> rational.approx_max_den 100 phi;
[1L%1L, 3L%2L, 8L%5L, 21L%13L, 55L%34L, 144L%89L]

(The symbol phi was defined in Example 43.)

Example 52  Rational interval surrounding $\pi$:

> let i_Pi = rational.interval_max_den 100 pi ; i_Pi;
interval::Ivl (311L%99L) (22L%7L)
> double (lower i_Pi); pi;
3.14141414141414
3.14159265358979
3.14285714285714

Example 53  Rational interval surrounding the golden ratio $\phi$:

> rational.interval_max_den 1000 phi;
interval::Ivl (987L%610L) (1597L%987L)

(The symbol phi was defined in Example 43.)

To approximate for a particular (rather than bounded) denominator, use round to multiple instead (see Rounding to Multiples).

20.12  Decomposition

There is more than one way to ‘decompose’ a rational number into its ‘components’. It might be split into an integer and a fraction part — see Integer and Fraction Parts; or sign and absolute value — see Absolute Value and Sign; or numerator and denominator — see ‘Deconstructors’.
20.13 Continued Fractions

20.13.1 Introduction

In “pure-rational”, a continued fraction $a_0 + \frac{1}{(a_1 + \frac{1}{(a_2 + \cdots + 1/a_n)})}$ where $\forall i > 0 \cdot a_i \neq 0$, is represented by $[a_0, a_1, a_2, \ldots, a_n]$. A ‘simple’ continued fraction is one in which $\forall i \cdot a_i \in \mathbb{Z}$ and $\forall i > 0 \cdot a_i > 0$.

Simple continued fractions for rationals are not quite unique since $[a_0, a_1, \ldots, a_n, 1] = [a_0, a_1, \ldots, a_{n+1}]$. We will refer to these as the ‘non-standard’ and ‘standard’ forms, respectively. The following functions return the standard form.

20.13.2 Generating Continued Fractions

Exact

$rational::\text{continued_fraction} \ q$

Find ‘the’ (exact) continued fraction of a rational (including, trivially, integer) value $q$.

Example 54 The rational 1234/1001:

> continued_fraction (1234%1001);
[1L,4L,3L,2L,1L,1L,1L,8L]
> evaluate_continued_fraction ans;
1234L%1001L

Inexact

$rational::\text{continued_fraction_max_terms} \ n \ r$

Find up to $n$ initial terms of continued fraction of the value $r$ with the ‘remainder’, if any, in the final element. (If continued_fraction_max_terms $n \ r$ returns a list of length $n$ or less, then the result is exact.)

Example 55 First 5 terms of the continued fraction for the golden ratio $\phi$:

> continued_fraction_max_terms 5 phi;
[1.0,1.0,1.0,1.0,1.0,1.61803398874989]
> evaluate_continued_fraction ans;
1.61803398874989

(The symbol phi was defined in Example 43.)

$rational::\text{continued_fraction_epsilon} \ \epsilon \ r$

Find enough of the initial terms of a continued fraction to within $\epsilon$ of the value $r$ with the ‘remainder’, if any, in the final element.

Example 56 First few terms of the value $\sqrt{2}$:

> continued_fraction_epsilon .001 (sqrt 2);
[1.0,2.0,2.0,2.0,2.0,2.41421356237241]
> map double (convergents ans);
[1.0,1.5,1.4,1.41666666666667,1.41379310344828,1.41421356237309]
20.13.3 Evaluating Continued Fractions

rational::`evaluate_continued_fraction` aa

Fold a continued fraction aa into the value it represents. This function is not limited to simple continued fractions. (Exact simple continued fractions are folded into a rational.)

Example 57 The continued fraction [1, 2, 3, 4] and the non-standard form [4, 3, 2, 1]:

```plaintext
> evaluate_continued_fraction [1,2,3,4]; 43L%30L
> continued_fraction ans; [1L,2L,3L,4L]
> evaluate_continued_fraction [4,3,2,1]; 43L%10L
> continued_fraction ans; [4L,3L,3L]
```

Convergents

rational::`convergents` aa

Calculate the convergents of the continued fraction aa. This function is not limited to simple continued fractions.

Example 58 Convergents of a continued fraction approximation of the value √2:

```plaintext
> continued_fraction_max_terms 5 (sqrt 2); [1.0,2.0,2.0,2.0,2.0,2.41421356237241]
> convergents ans; [1.0,1.5,1.4,1.41666666666667,1.41379310344828,1.41421356237309]
```

20.14 Rational Complex Numbers

Pure together with `rational.pure` provide various types of number, including integers (`Z`), doubles (`R`, roughly), complex numbers (`C`) and Gaussian integers (`Z[i]`), rationals (`Q`) and rational complex numbers (`Q[i]`).

Functions concerning ‘complex numbers’ are named with ‘comp’, whereas functions concerning ‘complexity’ (see Complexity) are named with ‘cplx’.

20.14.1 Rational Complex Constructors and ‘Deconstructors’

Complex numbers can have rational parts.

Example 59 Forming a rational complex:

```plaintext
> 1 +: 1 * (1%2); 1+:1L%2L
> ans * ans; 3L%4L+:1L%1L
```
And rational numbers can be given complex parts.

Example 60 Complex rationals and complicated rationals:

```plaintext
> (1 +% 2) % (3 +% 4);
1L%2L+%2L%2L
> ans * (3 +% 4);
1L%1L+%2L%1L
> ((4%1) * (0 +% 1)) % 2;
0L%1L+%2L%1L
> ((4%1) * (0 +% 1)) % (1%2);
0L%1L+%8L%1L
> ((4%1) * (0 +% 1)) % (1 + (1%2) * (0 +% 1));
8L%5L+%16L%5L
> ans * (1+(1%2) * (0 +% 1));
0L%1L+%4L%1L
> ((4%1) * (0 +% 1)) / (1 + (1%2) * (0 +% 1));
1.6 +% 3.2
```

The various parts of a complex rational may be deconstructed using combinations of num and den and the standard functions re and im.

Thus, taking real and imaginary parts first, a rational complex number may be considered to be \((x_n / x_d) + (y_n / y_d) * i\) with \(n_x, n_y, d_x, d_y \in \mathbb{Z}\).

A rational complex number may also be decomposed into its ‘numerator’ and ‘denominator’, where these are both integral complex numbers, or ‘Gaussian integers’, and the denominator is a minimal choice in some sense.

One way to do this is so that the denominator is the minimum positive integer. The denominator is a complex number with zero imaginary part.

Thus, taking numerator and denominator parts first, a rational complex number may be considered to be \((n_x + n_y * i) / (d + 0 * i)\) with \(n_x, n_y, d \in \mathbb{Z}\).

Another way to do this is so that the denominator is a Gaussian integer with minimal absolute value. Thus, taking numerator and denominator parts first, a rational complex number may be considered to be \((n_x + n_y * i) / (d_x + d_y * i)\) with \(n_x, n_y, d_x, d_y \in \mathbb{Z}\).

The \(d_x, d_y\) are not unique, but can be chosen such that \(d_x > 0\) and either \(|d_y| < d_x\) or \(d_y = d_x > 0\).

```plaintext
rational::num_den_nat c
given a complex rational or integer c, returns a pair (n, d) containing an integral complex (Gaussian integral) numerator n, and the smallest natural (i.e. positive integral real) complex denominator d, i.e. a complex number where \(\Re(d) \in \mathbb{Z}, \Re(d) > 0, \Im(d) = 0;\) i.e. the numerator and denominator of one ‘normalised’ form of c.

This is an inverse (up to equivalence) of rational as defined on integral complex pairs (see Constructors).

rational::num_den_gauss c
given a complex rational or integer c, returns a pair (n, d) containing an integral complex (Gaussian integral) numerator n, and an absolutely smallest integral complex de-
```
nominator \(d\) chosen s.t. \(\Re(d),=(d) \in \mathbb{Z}, \Re(d) > 0,\) and either \(|\Re(d)| < \Im(d)|\) or \(\Re(d) = \Im(d) > 0;\) i.e. the numerator and denominator of another ‘normalised’ form of \(c.\)

This is an inverse (up to equivalence) of rational as defined on integral complex pairs (see Constructors).

**rational::num_den** \(c\)

synonymous with num_den_gauss.

This is an inverse (up to equivalence) of rational as defined on integer pairs (see Constructors).

**num** \(c\)

given a complex rational or integer \(c\), returns just the numerator of the normalised form of \(c\) given by num_den \(c\).

**den** \(c\)

given a complex rational or integer \(c\), returns just the denominator of the normalised form of \(c\) given by num_den \(c\).

**Example 61** Rational complex number deconstruction:

```plaintext
> let cq = (1+2*i)%(3+3*i); cq;
1L%2L+:1L%6L
> (re cq, im cq);
1L%2L,1L%6L
> (num . re) cq;
1L
> (den . re) cq;
2L
> (num . im) cq;
1L
> (den . im) cq;
6L
> let (n_nat,d_nat) = num_den_nat cq;
> (n_nat, d_nat);
3+:1,6+:0
> n_nat % d_nat;
1L%2L+:1L%6L
> abs d_nat;
6.0
> let (n, d) = num_den_gauss cq; (n, d);
1L+:2L,3L+:3L
> let (n,d) = num_den cq; (n, d);
1L+:2L,3L+:3L
> n % d;
1L%2L+:1L%6L
> abs d;
4.24264068711928
> (re . num) cq;
1L
> (im . num) cq;
2L
```
20.14.2 Rational Complex Type and Value Tests

Beware that `intcompvalp` and `ratcompvalp` may return 1 even if the value is of complex type with double parts. However, these functions may be combined with `exactp`.

**`complexp x`**  
standard function; returns whether x is of complex type.

**`compvalp x`**  
standard function; returns whether x has a complex value (∈ C = R[i]).

**rational::`ratcompvalp x`**  
returns whether x has a rational complex value (∈ Q[i]).

**rational::`intcompvalp x`**  
returns whether x has an integral complex value (∈ Z[i]), i.e. a Gaussian integer value.

**Example 62** Rational complex number value tests:

```plaintext
> let l = [9, 9%1, 9%2, 4.5, sqrt 2, 1+:1, 1%2+:1, 0.5+:1, inf, nan];
> map exactp l;
[1,1,1,0,0,1,1,0,0,0]
> map inexactp l;
[0,0,0,1,1,0,1,1,1]
> map complexp l;
[0,0,0,0,0,0,0,0,0,0]
> map compvalp l;
[1,1,1,1,1,1,1,1,1,1]
> map (\x -> (exactp x and compvalp x)) l; // "has exact complex value"
[1,1,1,0,0,1,1,0,0,0]
> map ratcompvalp l;
[1,1,1,1,1,1,1,0,0,0]
> map (\x -> (exactp x and ratcompvalp x)) l;
[1,1,1,0,0,1,1,0,0,0]
> map intcompvalp l;
[1,1,0,0,0,1,0,0,0,0]
> map (\x -> (exactp x and intcompvalp x)) l;
[1,1,0,0,0,1,0,0,0,0]
> map ratvalp l;
[1,1,1,1,0,0,0,0,0,0]
> map (\x -> (exactp x and ratvalp x)) l;
[1,1,1,0,0,0,0,0,0,0]
> map intvalp l; // for comparison
[1,1,0,0,0,0,0,0,0,0]
> map (\x -> (exactp x and intvalp x)) l;
[1,1,0,0,0,0,0,0,0,0]
```

See 'Type and Value Tests'... for some details of rational type and value tests.
20.14.3 Rational Complex Arithmetic Operators and Relations

The standard arithmetic operators (+), (−), (∗), (∗/), (%), (), (==) and (!=) are overloaded to have at least one complex and/or rational operand, but (<), (<=), (>), (>=) are not, as complex numbers are unordered.

Example 63 Rational complex arithmetic:

```
> let w = 1%2 +: 3%4;
> let z = 5%6 +: 7%8;
> w + z;
4L%3L+:13L%8L
> w % z;
618L%841L+:108L%841L
> w / z;
0.734839476813318+:0.128418549346017
> w ^ 2;
-0.3125+:0.75
> w == z;
0
> w == w;
1
```

20.14.4 Rational Complex Maths

The standard functions re and im work with rational complex numbers (see Rational Complex Constructors and ‘Deconstructors’).

The standard functions polar, abs and arg work with rational complex numbers, but the results are inexact.

Example 64 Rational complex maths:

```
> polar (1%2+:1%2);
0.707106781186548<:0.785398163397448
> abs (4%2+:3%2);
2.5
> arg (-1%1);
3.14159265358979
```

There are some additional useful functions for calculating with rational complex numbers and more general mathematical values.

```
rational::norm_gauss c
returns the Gaussian norm ||c|| of any complex (or real) number c; this is the square of the absolute value, and is returned as an (exact) integer.
```

```
rational::div_mod_gauss n d
performs Gaussian integer division, returning (q, r) where q is a (not always unique) quotient, and r is a (not always unique) remainder. q and r are such that n = q * d + r and ||r|| < ||d|| (equivalently, |r| < |d|).
```
rational::n_div_gauss d
returns just a quotient from Gaussian integer division as produced by div_mod_gauss n d.

rational::n_mod_gauss d
returns just a remainder from Gaussian integer division as produced by div_mod_gauss n d.

rational::gcd_gauss c1 c2
returns a GCD G of the Gaussian integers c1,c2. This is chosen so that s.t. ℜ(G) > 0,
and either |ℑ(G)| < ℜ(G) or ℑ(G) = ℜ(G) > 0;

rational::euclid_gcd zerofun modfun x y
returns a (non-unique) GCD calculated by performing the Euclidean algorithm on the
values x and y (of any type) where zerofun is a predicate for equality to 0, and modfun
is a binary modulus (remainder) function.

rational::euclid_alg zerofun divfun x y
returns (g, a, b) where the g is a (non-unique) GCD and a, b are (arbitrary, non-unique)
values such that a * x + b * y = g calculated by performing the generalised Euclidean
algorithm on the values x and y (of any type) where zerofun is a predicate for equality
to 0, and div is a binary quotient function.

Example 65 More rational complex and other maths:

```lisp
> norm_gauss (1 +: 3);
10
> abs (1 +: 3);
3.16227766016838

> a * 25 + b * 15;
5

### 20.14.5 Rational Complex Type Simplification

- **rational::comp_simplify c**
  - Returns q with complex numbers simplified to reals, if possible.
- **rational::ratcomp_simplify c**
  - Returns q with rationals simplified to integers, and complex numbers simplified to reals, if possible.

**Example 66** Rational complex number type simplification:

> let l = [9+:1, 9%1+:1, 9%2+:1, 4.5+:1, 9%1+:0, 9%2+:0, 4.5+:0.0];
> l;
[9+:1,9%1+:1,9%2L+:1,4.5+:1,9%1L+:0,9%2L+:0,4.5+:0.0]
> map comp_simplify l;
[9+:1,9%1L+:1,9%2L+:1,4.5+:1,9%1L,9%2L,4.5+:0.0]
> map ratcomp_simplify l;
[9+:1,9+:1,9%2L+:1,4.5+:1,9,9%2L,4.5+:0.0]

See ‘Rational Type Simplification’ for some details of rational type simplification.

### 20.15 String Formatting and Evaluation

#### 20.15.1 The Naming of the String Conversion Functions

There are several families of functions for converting between strings and rationals.

The functions that convert from rationals to strings have names based on that of the standard function `str`. The `str_*` functions convert to a formatted string, and depend on a ‘format structure’ parameter (see Internationalisation and Format Structures). The `strs_*` functions convert to a tuple of string fragments.

The functions that convert from strings to rationals have names based on that of the standard function `eval` (`val` in Q). The `val_*` functions convert from a formatted string, and depend on a format structure parameter. The `sval_*` functions convert from a tuple of string fragments.

There are also `join_*` and `split_*` functions to join string fragments into formatted strings, and to split formatted strings into string fragments, respectively; these depend on a format...
structure parameter. These functions are not always invertible, because some of the functions reduce an error term to just a sign, e.g. \texttt{str\_real\_approx\_dp} may round a value. Thus sometimes the \texttt{join\_\*} and \texttt{split\_\*} pairs, and the \texttt{str\_\*} and \texttt{val\_\*} pairs are not quite mutual inverses.

### 20.15.2 Internationalisation and Format Structures

Many of the string formatting functions in the following sections are parameterised by a ‘format structure’. Throughout this document, the formal parameter for the format structure will be \texttt{fmt}. This is simply a record mapping some string ‘codes’ to functions as follows. The functions are mostly from strings to a string, or from a string to a tuple of strings.

- \texttt{"sm"} a function mapping a sign and an unsigned mantissa (or integer) strings to a signed mantissa (or integer) string.
- \texttt{"se"} a function mapping a sign and an unsigned exponent string to a signed exponent string.
- \texttt{"-s"} a function mapping a signed number string to a pair containing a sign and the unsigned number string.
- \texttt{"gi"} a function mapping an integer representing the group size and an integer string to a grouped integer string.
- \texttt{"gf"} a function mapping an integer representing the group size and a fraction-part string to a grouped fraction-part string.
- \texttt{"-g"} a function mapping a grouped number string to an ungrouped number string.
- \texttt{"zi"} a function mapping an integer number string to a number string. The input string representing zero integer part is "", which should be mapped to the desired representation of zero. All other number strings should be returned unaltered.
- \texttt{"zf"} a function mapping a fraction-part number string to a number string. The input string representing zero fraction part is "", which should be mapped to the desired representation of zero. All other number strings should be returned unaltered.
- \texttt{"ir"} a function mapping initial and recurring parts of a fraction part to the desired format.
- \texttt{"-ir"} a function mapping a formatted fraction part to the component initial and recurring parts.
- \texttt{"if"} a function mapping an integer string and fraction part string to the radix-point formatted string.
- \texttt{"-if"} a function mapping a radix-point formatted string to the component integer fraction part strings.
- \texttt{"me"} a function mapping a mantissa string and exponent string to the formatted exponential string.
- \texttt{"-me"} a function mapping a formatted exponential string to the component mantissa and exponent strings.
"e" a function mapping an ‘error’ number (not string) and a number string to a formatted number string indicating the sign of the error.

"-e" a function mapping a formatted number string indicating the sign of the error to the component ‘error’ string (not number) and number strings.

Depending upon the format structure, some parameters of some of the functions taking a format structure may have no effect. For example, an intGroup parameter specifying the size of the integer digit groups will have no effect if the integer group separator is the empty string.

rational::create_format options is a function that provides an easy way to prepare a ‘format structure’ from the simpler ‘options structure’. The options structure is another record, but from more descriptive strings to a string or tuple of strings.

For example, format.uk is generated from options.uk as follows:

```java
public options.uk;
const options.uk =
{
    "sign" => ("-","",""),   // alternative: ("-","","")
    "exponent sign" => ("-","",""),  // alternative: ("-","","")
    "group separator" => ",",     // might be " " or "." or " " elsewhere
    "zero" => "0",
    "radix point" => ".",         // might be " ", " ")
    "fraction group separator" => ",",
    "fraction zero" => "0",       // alternative: ""
    "recur brackets" => "[...]",
    "exponent" => "*10^",         // (poor) alternative: "e"
    "error sign" => ("-","",""),
    "error brackets" => ("(","")")
};

public format.uk;
const format.uk = create_format options.uk;
```

The exponent string need not depend on the radix, as the numerals for the number radix in that radix are always “10”.

Beware of using “e” or “E” as an exponent string as these have the potential of being treated as digits in, e.g., hexadecimal.

Format structures do not have to be generated via create format; they may also be constructed directly.

**20.15.3 Digit Grouping**

Some functions take group parameters. A value of 0 means “don’t group”.

---

658 20.15 String Formatting and Evaluation
20.15.4 Radices

The functions that produce a decimal expansion take a Radix argument. The fraction parts are expanded in that radix (or ‘base’), in addition to the integer parts. The parameter Radix is not restricted to the usual [2, 8, 10, 16], but may be any integer from 2 to 36; the numerals (‘digits’) are chosen from ["0", ... , "9", "A", ..., "Z"]. The letter-digits are always upper case. The functions do not attach a prefix (such as “0x” for hexadecimal) to the resulting string.

20.15.5 Error Terms

Some functions return a value including an ‘error’ term (in a tuple) or sign (at the end of a string). Such an error is represents what the next digit would be as a fraction of the radix.

Example 67 Error term in the tuple of string ‘fragments’:

```
> strs_real_approx_sf 10 floor 3 (234567%100000);
"+","2","34",567%1000L
> strs_real_approx_sf 10 ceil 3 (234567%100000);
"+","2","35",(-433)%1000L
```

(See the function `strs_real_approx_sf`.)

In strings, only the sign of the error term is given. A “+” should be read as “and a bit more”; “-” as “but a bit less”.

Example 68 Error sign in the string:

```
> str_real_approx_sf format_uk 10 0 0 floor 3 (234567%100000);
"2.34(+)"
> str_real_approx_sf format_uk 10 0 0 ceil 3 (234567%100000);
"2.35(-)"
```

(See the function `str_real_approx_sf`.)

20.16 Q <-> Fraction String (“i + n/d”)

20.16.1 Formatting to Fraction Strings

```
rational::str_vulgar q
returns a String representing the rational (or integer) q in the form
•“[−]n/d”
```

```
rational::str_vulgar_or_int q
returns a String representing the rational (or integer) q in one of the forms
•“[−]n/d”
•“[−]i”
```

```
rational::str_mixed q
returns a String representing the rational (or integer) q in one of the forms
```

20.15.4 Radices
The fraction string representations:

```haskell
> let l = iterwhile (<= 3%2) (+ (1%2)) (-3%2);
> l;
[(-3L)%2L,(-1L)%1L,(-1L)%2L,0L%1L,1L%1L,3L%2L]
> map str_vulgar l;
["-3L/2L","-1L/1L","-1L/2L","0L/1L","1L/2L","3L/2L"]
> map str_vulgar_or_int l;
["-3L/2L","-1L","-1L/2L","0L","1L/2L","1L","3L/2L"]
> map str_mixed l;
["-(1L+1L/2L)","-1L","-1L/2L","0L","1L/2L","1L","1L+1L/2L"]
```

These might be compared to the behaviour of the standard function `str`.

```
str x
returns a string representing the value x.
```

Example 70 The standard function `str`:

```haskell
> map str l;
["(-3L)%2L","(-1L)%1L","(-1L)%2L","0L%1L","1L%1L","3L%2L"]
```

20.16.2 Evaluation of Fraction Strings

`rational::val_vulgar` str
returns a rational q represented by the string str in the form

\[ -\frac{n}{d} \]

Such strings can also be evaluated by the `val_mixed` function.

```
rational::val_mixed` str
returns a rational q represented by the string str
\[ i + \frac{n}{d} \]
\[ -\left(i + \frac{n}{d}\right) \]
\[ -\frac{n}{d} \] — thus `val_mixed` strictly extends `val_vulgar`
\[ -\left[i\right] \]
```

Example 71 Evaluating fraction strings:

```haskell
> val_vulgar ".-22/7";
(-22L)%7L
> val_mixed "1L+5L/6L";
11L%6L
```
These might be compared to the behaviour of the standard function eval.

```plaintext
eval s
```
evaluates the string s.

**Example 72** The standard function eval:

```plaintext
> eval "1+5%6";
11L%6L
> eval "1L+5L/6L";
1.83333333333333
```

### 20.17 Q <-> Recurring Numeral Expansion String (“I.FR”)

See [Internationalisation and Format Structures](#) for information about the formatting structure to be supplied in the `fmt` parameter.

#### 20.17.1 Formatting to Recurring Expansion Strings

```plaintext
rational::str_real_recur fmt radix intGroup q
```
returns a string (exactly) representing the rational (or integer) q as base-Radix expansion of one the forms

- `“[−]int.fraction”`
- `“[−]int.init frac part[smallest recurring frac part ...]”`

Note that there is no fracGroup parameter.

Beware that the string returned by this function can be very long. The length of the recurring part of such a decimal expansion may be up to one less than the simplest denominator of q.

**Example 73** The recurring radix expansion-type string representations:

```plaintext
> str_real_recur format_uk 10 3 (4000001%4); // grouped with commas
"1,000,000.25"
> str_real_recur format_uk 10 0 (4000001%4); // no grouping
"1000000.25"
> str_real_recur format_uk 10 3 (1000000%3);
"333,333.333..."
> str_real_recur format_uk 10 3 (1000000%7);
"142,857,142857...
> str_real_recur format_uk 10 3 (-1%700);
"-0.00[142857...]
> str_real_recur format_uk 10 3 (127%128);
"0.9921875"
> str_real_recur format_uk 2 4 (-127%128);
"-0.111111"
> str_real_recur format_uk 16 4 (127%128);
"0.FE"
> str_real_recur format_uk 10 0 (70057%350); // 1%7 + 10001%50;
"200.16[285714...]
```
The function allows expansion to different radices (bases).

**Example 74** The recurring radix expansion in decimal and hexadecimal:

```plaintext
> str_real_recur format_uk 10 0 (1%100);
"0.01"
> str_real_recur format_uk 16 0 (1%100);
"0.0[28F3C...]
```

**Example 75** The recurring radix expansion in duodecimal:

```plaintext
> str_real_recur format_uk 12 0 (1%100);
"0.0[15343A0B62A68781B059...]
```

Note that this bracket notation is not standard in the literature. Usually the recurring numerals are indicated by a single dot over the initial and final numerals of the recurring part, or an overline over the recurring part. For example $1/70 = 0.0'14285'7 = 0.0142857$ and $1/3 = 0.3$.

**rational**: `strs_real_recur` radix q
returns a quadruple of the four strings:

- the sign,
- integer part (which is empty for 0),
- initial fraction part
- and recurring fraction part (either and both of which may be empty).

**Example 76** The recurring radix expansion in decimal — the fragments:

```plaintext
> strs_real_recur 10 (100%7);  
"+", "14", ";", "285714"
> strs_real_recur 10 (-1%700);  
"-", ";", "00", "142857"
> strs_real_recur 10 (70057%350);  
"+", "200", "16", "285714"
```

This function may be used to also, e.g. format the integer part with comma-separated groupings.

**rational**: `join_str_real_recur` fmt intGroup sign i fracInit fracRecur
formats the parts in the quadruple returned by `strs_real_recur` to the sort of string as returned by `str_real_recur`.

### 20.17.2 Evaluation of Recurring Expansion Strings

The `str_*` and `val_*` functions depend on a ‘format structure’ parameter (fmt) such as `format uk`. Conversions may be performed between rationals and differently formatted strings if a suitable alternative format structure is supplied. See Internationalisation and Format Structures for information about formatting structures.
rational::val_real_recur fmt radix strg returns the rational q represented by the base-radix expansion string strg of one the forms
  •”[−]int.frac”
  •”[−]int.init frac part[recurring frac part ...]”

Example 77 Conversion from the recurring radix expansion-type string representations:

> val_real_recur format_uk 10 "-12.345";
(−2469L)%200L
> val_real_recur format_uk 10 "0.3";
3L%10L
> val_real_recur format_uk 10 "0.[3...]";
1L%3L
> val_real_recur format_uk 10 ".333[33...]";
1L%3L
> val_real_recur format_uk 10 ".[9...]";
1L%1L

rational::sval_real_recur radix sign iStr fracStr recurPartStr returns the rational q represented by the parts
  •sign
  •integer part
  •initial fraction part
  •recurring fraction part

rational::split_str_real_recurFmt strg returns a tuple containing the parts
  •sign
  •integer part
  •initial fraction part
  •recurring fraction part of one the forms - “[−]int.frac” - “[−]int.init frac part[recurring frac part ...]”

20.18  Q <-> Numeral Expansion String (“I.F × 10E”)

See Internationalisation and Format Structures for information about the formatting structure to be supplied in the fmt parameter.

The exponent string “*10^” need not depend on the radix, as the numerals for the number radix in that radix are always “10”.

20.18 Q <-> Numeral Expansion String (“I.F × 10E”)

663
20.18.1 Formatting to Expansion Strings

Functions for Fixed Decimal Places

\texttt{rational::str\_real\_approx\_dp} \ \texttt{fmt} \ \texttt{radix} \ \texttt{intGroup} \ \texttt{fracGroup} \ \texttt{roundfun} \ \texttt{dp} \ \texttt{q} \\
returns a string representing a numeral expansion approximation of \texttt{q} to \texttt{dp} decimal places, using rounding mode \texttt{roundfun} (see Rounding to Integer). \texttt{roundfun} is usually \texttt{round} or \texttt{round\_unbiased}. (\texttt{dp} may be positive, zero or negative; non-positive \texttt{dps} may look misleading — use e.g. scientific notation instead.)

\textbf{Example 78} Decimal places:

\begin{verbatim}
> str\_real\_approx\_dp format\_uk 10 3 3 round 2 (22\%7);
"3.14(+)"
> str\_real\_approx\_dp format\_uk 10 3 3 ceil 2 (22\%7);
"3.15(-)"
\end{verbatim}

\texttt{rational::strs\_real\_approx\_dp} \ \texttt{radix} \ \texttt{roundfun} \ \texttt{do} \ \texttt{q} \\
returns a tuple of strings

- sign
- integer part
- fraction part

representing an expansion to a number of decimal places, together with

- the rounding “error”: a fraction representing the next numerals.

\textbf{Example 79} Decimal places — the fragments:

\begin{verbatim}
> str\_real\_approx\_dp 10 round 2 (22\%7);
"+","3","14",2L\%7L
> str\_real\_approx\_dp 10 ceil 2 (22\%7);
"+","3","15",(-5L)\%7L
\end{verbatim}

\texttt{rational::join\_str\_real\_approx} \ \texttt{fmt} \ \texttt{intGroup} \ \texttt{fracGroup} \ \texttt{sign} \ \texttt{i} \ \texttt{frac} \ \texttt{err} \\
formats the parts in the quadruple returned by \texttt{strs\_real\_approx\_dp} or \texttt{strs\_real\_approx\_sf} to the sort of string as returned by \texttt{str\_real\_approx\_dp} or \texttt{str\_real\_approx\_sf}.

Functions for Significant Figures

\texttt{rational::str\_real\_approx\_sf} \ \texttt{fmt} \ \texttt{radix} \ \texttt{intGroup} \ \texttt{fracGroup} \ \texttt{roundfun} \ \texttt{sf} \ \texttt{q} \\
returns a string representing a numeral expansion approximation of \texttt{q} to \texttt{sf} significant figures, using rounding mode \texttt{roundfun} (see Rounding to Integer).

\texttt{roundfun} is usually \texttt{round} or \texttt{round\_unbiased}. (\texttt{sf} must be positive.)

\textbf{Example 80} Significant figures:

\begin{verbatim}
> str\_real\_approx\_sf format\_uk 10 3 3 floor 2 (22\%7);
"3.1(+)"
\end{verbatim}
> str_real_approx_sf format_uk 10 3 3 floor 2 ((-22)%7); 
"-3.2(+)

rational::strs_real_approx_sf radix roundfun sf q
returns a tuple of strings

• sign,
• integer part,
• fraction part, representing an expansion to a number of significant figures, together with
• the rounding “error”: a fraction representing the next numerals

rational::join_str_real_approx
see join_str_real_approx.

Functions for Scientific Notation and Engineering Notation

rational::str_real_approx_sci fmt radix intGroup fracGroup roundfun sf q
returns a string expansion with a number of significant figures in scientific notation, using rounding mode roundfun (see Rounding to Integer).

(sf must be positive; expStep is usually 3, radix is usually 10, roundfun is usually round or round_unbiased; str_real_approx_sci is equivalent to str_real_approx_eng (below) with expStep = 1.)

rational::strs_real_approx_sci radix roundfun sf q
returns a tuple of strings:

• sign of mantissa,
• integer part of mantissa,
• fraction part of mantissa,
• sign of exponent,
• exponent magnitude

representing an expansion to a number of significant figures in scientific notation together with

• the rounding “error”: a fraction representing the next numerals.

rational::str_real_approx_eng fmt expStep radix intGroup fracGroup round sf q
returns a string expansion with a number of significant figures in engineering notation, using rounding mode roundfun.

The ExpStep parameter specifies the granularity of the exponent; specifically, the exponent will always be divisible by expStep.

(sf must be positive; expStep is usually 3 and must be positive, radix is usually 10, roundfun is usually round or round_unbiased.)
Example 81 Engineering notation:

\[ \text{str\_real\_approx\_eng format\_uk 3 10 3 3 round 7 (rational 999950);} \]
\[ "999.950,0\times10^3" \]
\[ \text{str\_real\_approx\_eng format\_uk 3 10 3 3 round 4 999950;} \]
\[ "1.000\times10^6(-)" \]

rational::strs\_real\_approx\_eng expStep radix roundfun sf q
returns a tuple of strings:

- sign of mantissa,
- integer part of mantissa,
- fraction part of mantissa,
- sign of exponent,
- exponent magnitude

representing an expansion to a number of significant figures in engineering notation together with

- the rounding “error”: a fraction representing the next numerals.

Example 82 Engineering notation — the fragments:

\[ \text{strs\_real\_approx\_eng 3 10 round 7 (rational 999950);} \]
\[ "\+", "999", "9500", \+", "3", 0\%1L \]
\[ \text{strs\_real\_approx\_eng 3 10 round 4 999950;} \]
\[ "\+", "1", "000", \+", "6", (-1L)\%20L \]

rational::join\_str\_real\_eng fmt intGroup fracGroup mantSign mantI mantFrac expSign expI err
formats the parts in the quadruple returned by strs\_real\_approx\_eng or
strs\_real\_approx\_sci to the sort of string as returned by str\_real\_approx\_eng or
str\_real\_approx\_sci.

20.18.2 Evaluation of Expansion Strings

The str\_* and val\_* functions depend on a ‘format structure’ parameter (fmt) such as format uk. Conversions may be performed between rationals and differently formatted strings if a suitable alternative format structure is supplied. See Internationalisation and Format Structures for information about formatting structures.

rational::val\_real\_eng fmt radix strg
returns the rational q represented by the base-radix expansion string strg of one the forms

- “[−]int.frac”
- “[−]int.frac[−]exponent”

Example 83 Conversion from the recurring radix expansion-type string representations:
> val_real_eng format_uk 10 "-12.345";
(-2469L)%200L
> val_real_eng format_uk 10 "-12.345*10^2";
(-2469L)%2L

rational::sval_real_eng radix signStr mantIStr mantF racStr expSignStr expStr
returns the rational q represented by the parts
  • sign
  • integer part of mantissa
  • fraction part of mantissa
  • sign of exponent
  • exponent

rational::split_str_real_eng fmt strg
returns a tuple containing the string parts
  • sign
  • integer part of mantissa
  • fraction part of mantissa
  • sign of exponent
  • exponent
  • the “error” sign
of one the forms
  • “[−]int.frac”
  • “[−]int.frac \times 10^{[−]exponent}”

These functions can deal with the fixed decimal places, the significant figures and the scientific notation in addition to the engineering notation.

20.19 Numeral String -> Q — Approximation

This section describes functions to approximate by a rational a real number represented by a string. See R -> Q — Approximation for approximation by a rational of a double.

The str_* and val_* functions depend on a ‘format structure’ parameter (fmt) such as format uk. Conversions may be performed between rationals and differently formatted strings if a format structure is supplied. See Internationalisation and Format Structures for information about formatting structures.

rational::val_eng_approx_epsilon fmt radix epsilon strg
Find the least complex rational approximation q to the number represented by the base-radix expansion string str in one of the forms
that is $\epsilon$-close. That is find a $q$ such that $|q - \text{eval str}| \leq \epsilon$.

Example 84 Rational from a long string:

```cpp
def str = "123.456,789,876,543,212,345,678,987,654,321*10^27";
def x = val_real_eng format_uk 10 str;
def x;
def q = val_eng_approx_epsilon format_uk 10 (1%100) str;
def q;
def double (x - q);
def str_real_approx_eng format_uk 3 10 3 3 round 30 q;
def str_real_approx_eng format_uk 3 10 3 3 round 42 q;
def double q;
def rational::val_eng_interval_epsilon fmt radix epsilon str
```

Example 85 Other rationals from a long string:
> val_eng_approx_epsilon format_uk 10 (1%100) strg;
1975308638024691397530863802469L%16L
> val_eng_interval_epsilon format_uk 10 (1%100) strg;
interval::Ivl (3086419746913580308641974691358L%25L)
(3456790116543209945679011654321L%28L)
> val_eng_approx_max_den format_uk 10 100 strg;
999999998000000019999998000000L%81L
> val_eng_interval_max_den format_uk 10 100 strg;
interval::Ivl 999999998000000019999998000000L%81L

Chapter 21

Computer Algebra with Pure: A Reduce Interface

Version 0.4, April 11, 2018

Albert Graef <aggraef@gmail.com>
Kurt Pagani <kp@scios.ch>

One of Pure’s distinguishing features as a term rewriting programming language is that it makes the symbolic manipulation of expressions very easy and convenient. It is thus a natural environment for hosting a full-featured computer algebra system (CAS). Computer algebra systems are complex pieces of software featuring advanced algorithms for simplification of algebraic expressions, symbolic integration, equation solving and much more. Reimplementing all these algorithms in Pure would be a major undertaking, to say the least. A much better option is to interface to an existing CAS which has already proven its worth to the scientific computing community, has been tested extensively and is known to be both reliable and efficient.

This is also the approach taken by Pure’s reduce module which interfaces to the well-known Reduce system. Along with Macsyma/Maxima, Reduce is one of the oldest computer algebra systems which has been around since the 1960s and is widely recognized as a state-of-the-art, powerful and efficient CAS. It is free/open source software distributed under a BSD-style license, actively maintained on its SourceForge website, and implementations exist for all major computing platforms. The reduce module makes the functionality of Reduce available in Pure in a seamless way. It uses an “embedded” version of Reduce in the form of a shared library which is easy to build from the Reduce sources; the Installation section below describes how to do this. More background information and a discussion of the interface can be found in the Embedding REDUCE thread on the Pure mailing list.

The interface can be found in the reduce.pure module. It has two parts, a low-level interface
which consists of a handful of C entry points supplied by the Reduce library, and a high-level interface which provides everything that the Pure programmer needs to use Reduce from Pure. Please note that at present this module is still experimental. But the basic functionality works, and you’re welcome to discuss the new interface on the mailing list and/or submit bug reports and patches.

21.1 Copying

pure-reduce is available under the same 2-clause BSD license as Reduce itself, please see the accompanying COPYING file and the reduce.pure file for details.

21.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-reduce-0.4.tar.gz.

You’ll need both the Reduce library (named reduce.so, reduce.dylib or reduce.dll, depending on the system you have) and a Reduce image file (reduce.img) to make this module work. A Makefile is included with this package so that you can build these yourself from the Reduce sources. (In principle, this only needs to be done once for the initial installation of this module, but you may want to repeat this procedure every once in a while to get the latest Reduce version.)

The full Reduce system is a big package, so we have packaged a stripped-down version of the Reduce source which contains all the bits and pieces needed to compile the Reduce library and image, and has also been patched up so that it compiles cleanly on recent Linux systems. At the time of this writing, you can find this package here:

(You may want to check the download section on the Pure website for newer revisions of this package, since we may update the package from time to time to the latest source from the Reduce svn repository.)

Unpack the reduce-algebra-csl tarball and move the resulting reduce-algebra directory into the pure-reduce source directory. Run make and then (if needed) make install in the pure-reduce directory (not in the reduce-algebra directory!). You should also run make check which performs a few tests in order to verify that the interface works ok (this can be done without installing the package, but needs the Reduce image and library).

For convenience, the Makefile also has a make reduce target which builds a minimal Reduce executable. If you use that option, make install installs this executable along with the library and image files, so that you can then run Reduce directly from the command line by just typing reduce. Please note that this is a really minimalistic Reduce frontend which is most useful for testing purposes. (If you want the full Reduce version then you can find binary Reduce packages for various systems at SourceForge. But note that neither the minimalistic nor the full Reduce frontend is required for the pure-reduce module in any way.)
It is also possible to build the Reduce library and image directly from the latest source in the Reduce svn repository. You can check out the repository with the following command:

```
svn co svn://svn.code.sf.net/p/reduce-algebra/code/trunk reduce-algebra
```

This pulls down many hundreds of megabytes, so this may take a while. Once the checkout is finished, you’ll end up with a reduce-algebra directory which you can drop into the pure-reduce source directory and proceed with the compilation as described above. Note that if you go that route then you should be prepared to deal with compilation problems in the Reduce sources. Reduce is a big and complicated software, so the svn sources are not always in a state which guarantees smooth compilation on all supported systems. If you run into problems then please consider using our streamlined reduce-algebra-csl package instead.

### 21.3 Low-Level Interface

The low-level interface is a straight wrapper of the C entry points provided by the Reduce library, also known as the “procedural” or PROC interface, for short. It uses an embedded version of Reduce which runs on a free and open-source Lisp flavour known as CSL (Codemist Standard Lisp). The external C routines are all declared in the reduce namespace. Normally you shouldn’t have to call these functions directly, since we provide a high-level, idiomatic Pure interface which makes calling Reduce from Pure much easier, see below.

### 21.4 High-Level Interface

The high-level interface provides a wrapper of the low-level PROC interface which makes calling Reduce from Pure easy and convenient. After installing the module, it can be imported in your Pure scripts as follows:

```
using reduce;
```

This starts up Reduce and makes the following variables and functions available in Pure.

#### 21.4.1 Starting and Stopping Reduce

**variable REDUCE_PATH**

This variable holds a colon-delimited search path used to locate the Reduce image file (see `reduce::start` below). By default this includes the current directory and the Pure library directory.

**reduce::start image::string args::smatrix**

Initializes the Reduce system. This is done automatically when loading this module, so normally you shouldn’t have to call this manually, unless the default image file wasn’t found or you want to restart the Reduce system with your own image file or your own set of options. When calling this operation manually, you need to specify the name of the Reduce image file and any desired extra arguments as a string vector. Unless the filename contains a slash, `reduce::start` searches the directories in `REDUCE_PATH` for the image file. An exception is raised if the image file isn’t found.
reduce::finish
   Finalizes the Reduce system. You can call this to release the resources of the Reduce
   system. (reduce::start also invokes this automatically if a Reduce instance is already
   running, so it isn’t necessary to call reduce::finish in this case.)

21.4.2 Maintenance Operations

reduce::verbosity n
   Sets the verbosity level; 0 means no messages at all (which is the default when using
   this module), and the following values may be or’ed together to pick what you need:
   
   1: messages whenever garbage collection happens
   2: messages whenever a module of code is loaded
   4: extra details in the garbage collector messages

reduce::switch name:string val::int
   Lets you change global Reduce options. This works like Reduce’s on and off declarations;
   please check the Reduce documentation for details.

reduce::capture flag::int

reduce::output
   Captures output from Reduce. If flag is nonzero, reduce::capture arranges for all
   output from Reduce to be buffered. The contents of the buffer can then be read using
   the reduce::output function which returns a string value. If flag is zero, capturing is
disabled so that output goes to stdout again.

reduce::feed s::string
   Feeds input to Reduce. Reduce will read input from the given string s, switching back
   to stdin after s has been processed.

reduce::load name::string
   Loads Reduce packages. This works like Reduce’s load_package command; please
   check the Reduce documentation for details.

reduce::in name::string
   Sources the given Reduce (.red) file. This works like the Lisp in function. Output is
captured using reduce::capture, see above.

21.4.3 Evaluation

For convenience, the following operations are in the default namespace:

simplify x
   This is the main entry point. It takes an algebraic expression in Pure format and tries to
   simplify it using Reduce. The result is then converted back to Pure format. Note that
   you need to quote x if you want to prevent it from being evaluated on the Pure side.

simplifyd x
   A variation of simplify which takes care of customary mathematical notation for limits,
   integrals and differentials, so that you can write stuff like d f/d x and \lim n \inf
(1/n) and have that expanded to the corresponding Reduce calls automatically. This also tries to support most of the idioms and variations of notation which can be seen in output of the Reduce tmprint module and which are commonly used in TeXmacs documents.

**lisp x**

This can be used to execute arbitrary Lisp code, which is sometimes necessary to perform special functions in the Reduce system. Note that you need to quote x if you want to prevent it from being evaluated on the Pure side. This is true, in particular, for the quote itself, which needs an extra level so that one quote goes through to the Lisp system (e.g.: lisp ("(a b c)"). For convenience, free symbols are quoted automatically, and Pure lists are mapped to corresponding Lisp lists and vice versa (so lisp [a,b,c] actually yields the same result as lisp ("(a b c)"). The result is always a Pure list or an atomic value.

**lispval x**

This converts a Pure expression to its Reduce equivalent, like simplify does, but without actually simplifying it. As with the other functions, you need to quote x if you want to prevent it from being evaluated on the Pure side. The result is the Pure representation of a Lisp form which can be passed as a value to other Lisp routines by employing the lisp function. (Normally this requires that you double-quote the expression so that it doesn’t get evaluated by the Lisp interpreter.) This function isn’t for casual usage, but may be useful if you need to pass a Reduce expression to some Lisp function which cannot be called through simplify.

**lispsym s::string**

This function creates a special Pure identifier for any symbol given as a string, even symbols which don’t conform to Pure syntax. This is sometimes needed to specify special Lisp symbols in calls to lisp, such as lisp (lispsym “oem-supervisor”). (Note that if such a special symbol occurs as a literal in a result returned by lisp or simplify then it will get mangled into a form which conforms to Pure syntax.)

**declare declsym [foo,bar,...]**

Declare symbols and their properties; please see the Declarations section in the Reduce manual for details. The second argument can also be a singleton symbol. In the present implementation, declsym must be one of:

- operator: declares an operator symbol;
- precedence: declares an infix operator and optionally specifies its precedence (giving the symbol priority over a second given symbol);
- antisymmetric, symmetric, even, odd, linear, noncom and nonzero: declares properties of already declared operator symbols;
- depend, nodepend, factor, remfac, order, korder: declares kernel dependencies and orders. These take both symbols and “kernels” as arguments (the latter are simple prefix expressions which denote irreducible subterms such as cos x; Reduce treats these more or less like variables in algebraic simplifications).

**precision prec::int**
Sets the internal Reduce precision in decimal digits for floating point calculations, and returns the previously set precision. This takes effect when rounded mode is enabled (reduce::switch "rounded" 1). Note that at present this only affects Reduce’s internal precision, floating point values are still returned as double precision numbers in Pure land.

plotreset
This is identical to the plotreset command provided by Reduce’s gnuplot interface, and is sometimes needed to reset the plot subsystem.

In Pure land, Reduce expressions are represented using Pure’s standard curried notation. Marshalling of numeric data works in a straightforward fashion and includes all natively supported Pure data types (machine ints, bigints, doubles, rationals and complex numbers). Some special conversions are applied to algebraic expressions to make arithmetic operations such as +, * etc. work as expected. In addition, the ==, =>, .. and := infix operators can be used to denote equations, replacement rules, ranges and assignments in Reduce, respectively. (Note that you may have to quote these in some cases so that they don’t get evaluated on the Pure side.) Also, Reduce’s arbconst n, arbint n and arbcomplex n terms can be mapped to Greek symbols αn, βn and ζn on the Pure side. (This may cause issues in environments without proper Unicode support, so it’s disabled by default.) For debugging purposes, all these automatic conversions can also be turned off on the output side with the ‘#! --disable mapped’ compilation pragma; this needs to be placed before the ‘using reduce;’ import clause to take effect. There are a number of other conditional compilation options which may be used to selectively turn off some of the conversions; please check the module source for details.

Lisp expressions are handled in a similar fashion, but here only a few basic Pure data types (integers, doubles, strings and lists) are converted to and from corresponding Lisp data. Function applications in Pure’s curried notation are mapped to corresponding Lisp forms. The result of invoking lisp is always one of the supported atomic types or a Pure list.

The lisp function is to be used with care. An orderly Pure exception is raised if you try to execute a non-existing Lisp function. But there are some internal functions in Reduce which aren’t very forgiving if you try to execute them with invalid arguments, and will most likely crash the Reduce system in such cases. You have been warned!

21.5 Basic Examples

Here is a simple example showing how to start up Reduce and do some calculations:

```plaintext
> using reduce;
Reduce (Free CSL version), 27-Sep-12 ...
> simplify $ df ((x+5)^3) x;
3*x^2+30*x+75
> simplify $ intg (exp (2*x)) x;
e^(2*x)/2
> simplify $ solve (x^2+7) x;
[x==sqrt 7*i,x==-sqrt 7*i]
```
Note that the result returned by `simplify` is always a quoted expression. If the expression can be further reduced on the Pure side, you'll have to use Pure's `eval` function to force its evaluation:

```
> using math;
> eval ans;
[x==0.0+:2.64575131106459,x==0.0+:-2.64575131106459]
```

The following example shows how you can do a simple plot using Reduce's `gnuplot` module:

```
> simplify $ plot [sin x/x, x=='(-20..20), terminal=="wxt"];

This pops up a wxWidgets window (terminal=="wxt") with a plot of the given function in it, see the screenshot below. The `x==’(-20..20)` argument specifies the desired range of the x variable (note that the range needs to be quoted so that it gets through to Reduce rather than being evaluated on the Pure side).

![Figure 21.1: Reduce gnuplot example.](image)

The same plot can be written to a PostScript file `sinc.ps` as follows:

```
> simplify $ plot [sin x/x, x=='(-20..20), terminal=="postscript", output=="sinc.ps"];

The `lisp` function can be used to execute Lisp code in the CSL interpreter hosting the Reduce system. Here are some basic examples. Note that, to be on the safe side, we just always quote the argument to `lisp` here to prevent its evaluation on the Pure side.

```
> lisp (’plus 2 3);
5
> lisp (’car (list a b c d e));
```
a

> lisp ('cdr [a,b,[c,d],e]);
[b,[c,d],e]

Lisp’s truth values are \texttt{t} and \texttt{nil}; the latter is just the empty list, so that’s what you get if a Lisp predicate evaluates to “false”:

> lisp ('lessp 5 3);
[]
> lisp ('greaterp 5 3);
t

Most simple kinds of Lisp calls should be doable that way, but don’t expect any miracles; the \texttt{lisp} function is provided to access special functionality in the “symbolic mode” of the Reduce system, not to turn Pure into a full-featured Lisp frontend. The following example illustrates how you can use the \texttt{lisp} function to declare an operator symbol and change or query its properties:

> lisp ('operator [myop]);
[]
> lisp ('flag [myop] odd);
[]
> lisp ('prop myop);
[odd:t,simpfn:simpiden]
> simplify (myop (-x));
-myop x

If you find it awkward to evaluate Lisp forms in Pure, you can also achieve the same with the \texttt{declare} function which covers most of the common Reduce declarations that might be needed:

> declare operator myop;
[]
> declare odd myop;
[]
> simplify (myop (-x));
-myop x

For basic Pure-based usage of Reduce, it’s convenient to have a simple read-eval-print loop which lets you type some declarations and expressions to be simplified (in Pure syntax), and takes care of all the quoting and invoking \texttt{simplify} for you. Here’s a little Pure script which does that:

```pure
using math, reduce, system;

/* You might want to replace this with the real readline if you have the 
 corresponding Pure module installed. See the red.pure script in the 
 distribution for details. */
myreadline prompt::string = fputs prompt stdout $$ fflush stdout $$ gets;

red = loop with
  // A simplistic REPL.
```
loop = case myreadline "->" of 
  s::string = process s $$ loop if ~null s;
  _ = () otherwise;
end;
// Get rid of trailing blanks and semicolons.
process s = process (init s) if any (==last s) [" ","];
// Process a declaration or REDUCE expression.
process s = case val s of 
  val _ = fputs "** syntax error\n" stderr if ~null lasterr;
  on flag = reduce::switch (str flag) 1;
  off flag = reduce::switch (str flag) 0;
  x@(declare _ _) = eval x;
  x = puts (str (simplify x)) otherwise;
end;
end;

Now you can run red at the Pure prompt and start typing the stuff you want to evaluate, one expression or declaration per line. Enter an empty line or Ctrl-D when you're done to return to the Pure command prompt.

> red;
> df ((x+5)^3) x
3*x^2+30*x+75
> intg (exp (2*x)) x
e^(2*x)/2
> on rounded
> solve (x^2+7==17) x
[x==3.16227766016838,x==-3.16227766016838]
> off rounded
> solve (x^2+7==17) x
[x==sqrt 10,x==-sqrt 10]
> declare operator myop
> declare odd myop
> myop (-x)
-myop x
> plot [sin x/x, x==(-20..20), terminal=="wxt"]
0
> ^D
()

Note that we barely scratched the surface here; Reduce is a very complex system with lots of capabilities. The following section explores some of these areas in more detail.

## 21.6 Examples by Topic

This is a small excerpt from the REDUCE User's Manual [REDUM], translated to Pure syntax. For any details we refer to that document. With this guide it should be straightforward to translate back and forth between Pure and REDUCE syntax for the invocation of REDUCE functions. The one thing you have to keep in mind is that Pure uses curried notation for function applications, so where a function is invoked as f(x,y,z) in REDUCE, you'll have to call
it as \( f \ x \ y \ z \) in Pure (with parentheses around each argument which is a compound expression).

The REDUCE User’s Manual as well as the documentation of each package and other valuable information may be found at: http://www.reduce-algebra.com/documentation.htm

### 21.6.1 Differentiation

The operator \( \text{df} \) is used to represent partial differentiation with respect to one or more variables.

\[ \text{df exprn [var <num>>] +} \]

Differentiation of the function \( x^2y^3z^4 \) with respect to \( x, y, z \), two, three and four times respectively, i.e \( \frac{\partial^2}{\partial x^2}y^3z^4 \):

\[
\begin{align*}
\text{> simplify $ \text{df} (x^2*y^3*z^4) x 2 y 3 z 4 ;$} \\
& 288
\end{align*}
\]

The derivative of \( \log \sin(x)^2 \):

\[
\begin{align*}
\text{> simplify $ \text{df} (\log(\sin(x))^2) x; $} \\
& 2*\cos x*\log(\sin x)/\sin x
\end{align*}
\]

Note the parentheses.

Suppose \( z(\cos(x), y) \). Let’s calculate \( \frac{\partial \sin(z)}{\partial \cos(x)} \) and \( \frac{\partial^2 z}{\partial x^2} \):

\[
\begin{align*}
\text{> declare depend \[z, \cos x, y\];} \\
\text{[\]} \\
\text{> simplify \{df (sin z) (cos x));} \\
\text{cos z*df z (cos x)} \\
\text{> simplify \{df (z^2) x);} \\
\text{2*df z x*z}
\end{align*}
\]

Note how to declare dependencies.

The results are \( \cos(z)\frac{\partial z}{\partial \cos(x)} \) and \( 2z\frac{\partial^2 z}{\partial x^2} \), respectively, as expected.

### 21.6.2 Integration

\( \text{INT} \) is an operator in REDUCE for indefinite integration using a combination of the Risch-Norman algorithm and pattern matching.

\[ \text{intg exprn var} \]

Note that in Pure the operator is called \( \text{intg} \) in order not to clash with the \( \text{int} \) conversion function.

Example 1:

\[
\int \frac{1}{ax + b} \, dx
\]
Example 2:

\[ I(a, b, n) = \int x^2(ax + b)^n dx \]

\[
> \text{simplify } \int \left( \frac{1}{a*x + b} \right) x; \\
\log \left( \frac{a*x + b}{a} \right)
\]

Example 2:

\[
I(a, b, n) = \int x^2(ax + b)^n dx
\]

\[
> I a b n = \text{simplify } \int (x^2(a*x + b)^n) x; \\
I a b n;
\]

\[
\frac{(a*x+b)^n*a^3*n^2*x^3+3*(a*x+b)^n*a^3*n*x^3+2*(a*x+b)^n*a^3*x^3+(a*x+b)^n+a^2*2*n^2*x^2+2*(a+x+b)^n+a+b^2*n*x^2+2*(a+x+b)^n*b^3/(a^3*n^3+6*a^3*n^2+11*a^3*n+6*a^3)}{(a^3*n^3+6*a^3*n^2+11*a^3*n+6*a^3)}
\]

\[
> I a b 0; \\
x^3/3
\]

\[
> I 0 b n; \\
b^n*x^3/3
\]

\[
> I a 0 k; \\
x^k*a^k*x^3/(k+3)
\]

Example 3:

\[
\int \frac{\sqrt{x} + \sqrt{x^2+1}}{x} dx
\]

\[
> \text{simplify } \int (\sqrt{x+\sqrt{x^2+1}})/x) x; \\
\int(\sqrt{\sqrt{x^2+1}+x})/x) x
\]

Apparently no solution was found. There is a package ALGINT in REDUCE which specifically deals with algebraic functions. The REDUCE User’s Manual [REDUM] says:

This package [...] will analytically integrate a wide range of expressions involving square roots where the answer exists in that class of functions. It is an implementation of the work described in J.H. Davenport [LNCS102].

\[
> \text{reduce::load } "\text{algint}" ; \\
0
\]

\[
> \text{simplify } \int (\sqrt{x+\sqrt{x^2+1}})/x) x; \\
\text{atan} ((\sqrt{(\sqrt{x^2+1}+x)})*\sqrt{(\sqrt{x^2+1}+x)} - \sqrt{(\sqrt{x^2+1}+x)})*x - \sqrt{(\sqrt{x^2+1}+x)})*2 + 2*\sqrt{(\sqrt{x^2+1}+x)} + \log(\sqrt{(\sqrt{x^2+1}+x)} - 1) - \log(\sqrt{(\sqrt{x^2+1}+x)} - 1)
\]

Note how to load packages.

21.6.2 Integration
21.6.3 Length, Map and Select

LENGTH is a generic operator for finding the length of compound objects. Besides lists and matrices, this also includes algebraic expressions. The MAP and SELECT operators let you manipulate such objects by applying a function to each element of the structure, or by picking the elements satisfying a given predicate function. Thus these operations serve pretty much the same purposes as # (or dim), map and filter in Pure, but in REDUCE they also work with the operands of an algebraic expression.

```
length exprn
map fun exprn
select fun exprn
```

```plaintext
> simplify $ length (a+b);
2
> simplify $ length (x^n+a*x+2);
3

> simplify $ 'map sqrt [1,2,3];
[1,2^(1/2),3^(1/2)]

> simplify $ 'map log [x^n,x^m,sin x];
[log (x^n),log (x^m),log (sin x)]
```

Note that map must be quoted if we want to evaluate it in REDUCE, since it’s also a function in Pure. In this case, we might as well do the calculation using Pure’s map; the result is exactly the same.

```plaintext
> simplify $ map sqrt [1,2,3];
[1,2^(1/2),3^(1/2)]

> simplify $ map log [x^n,x^m,sin x];
[log (x^n),log (x^m),log (sin x)]
```

If the function to be applied in calls to MAP or SELECT is a compound expression, it must either contain a single free variable (indicated with the ~ prefix, e.g. ~w) or a replacement rule of the form var => exprn. In either case the current elements are substituted for the free variable when the function is applied.

```plaintext
> simplify $ 'map (y=>df y x) [x^n,x^m,sin x];
[x^n*x/(n+1),x^m*x/(m+1),-cos x]

> simplify $ 'map (y=>intg y x) [x^n,x^m,sin x];
[x^n*x/(n+1),x^m*x/(m+1),-cos x]
```

Contrast this with Pure where the function argument to map is often specified as a lambda:

```plaintext
> simplify $ map (\y->df y x) [x^n,x^m,sin x];
[x^n*x/(n+1),x^m*x/(m+1),-cos x]

> simplify $ map (\y->intg y x) [x^n,x^m,sin x];
[x^n*x/(n+1),x^m*x/(m+1),-cos x]
```
In principle, the same correspondences also hold between REDUCE’s `select` and Pure’s `filter`. For instance, consider:

```latex
> simplify $ select (w=>evenp (deg w x)) [2*x^2,3*x^3,4*x^4];
[2*x^2,4*x^4]
```

The equivalent Pure `filter` is:

```latex
> filter (\w->simplify $ evenp (deg w x)) [2*x^2,3*x^3,4*x^4];
[2*x^2,4*x^4]
```

Note that REDUCE is now being called inside the predicate function, the rest of the processing is done in Pure.

Of course, if you want to apply `map`, `filter` and similar Pure functions to an algebraic expression, you’ll first have to extract its components as a list. Here’s a little Pure function which mimics the way in which `MAP` and `SELECT` decompose an expression:

```latex
terms x = case x of
  f@_ u v = collect f x with
    // Collect the operands of variadic Reduce operators.
    collect f (f@_ u v) = collect f u+collect f v;
    collect f x = [x] otherwise;
  end if any (===eval f) [(+),(-),(*),min,max];
  [u,v] if arity f == 2;
  _ = [x] otherwise;
end;
```

For instance, consider:

```latex
> simplify $ 'map (w=>w+1) (df ((x+y)^3) x);
[3*x^2+6*x*y+3*y^2+3]
```

With the help of `terms` we can also do this using Pure’s `map` as follows:

```latex
> map (+1) $ terms (simplify (df ((x+y)^3) x));
[3*x^2+6*x*y+3*y^2+3]
```

While the REDUCE version is shorter and only involves a single call to `simplify`, with a little bit of programming the Pure solution can be made just as convenient. More importantly, this method easily generalizes to other list operations. This makes it possible to apply Pure’s full arsenal of generic list functions which goes beyond what’s available in REDUCE.

### 21.6.4 Partial Fractions

The `PF` operator transforms an expression into a list of partial fractions with respect to the main variable. `PF` does a complete partial fraction decomposition.

```latex
pf expr var
```
Let us find the decomposition of:

\[ f(x) = \frac{2}{(x+1)^2(x+2)} \]

> let f = 2/((x+1)^2*(x+2));
> simplify $ pf f x;
[2/(x+2),(-2)/(x+1),2/(x^2+2*x+1)]

This means:

\[ f(x) = \frac{2}{x+2} + \frac{-2}{x+1} + \frac{2}{x^2+2x+1} \]

If one wants the denominators in factored form, one has to use the switch off exp:

> reduce::switch "exp" 0 ;
0
> simplify $ pf f x;
[2/(x+2),(-2)/(x+1),2/(x+1)^2]

Note how the value of a Reduce switch is changed in Pure.

### 21.6.5 Solving

SOLVE is an operator for solving one or more simultaneous algebraic equations. It is used with the syntax:

\[ \text{solve} \ expr \ [\text{var} \mid \text{varlist}] \]

where expr is a list of one or more expressions. Each expression is an algebraic equation, or is the difference of the two sides of the equation.

Example 1:

Find the solutions to

\[ \log(\sin(x + 3))^5 = 8 \]

> let eqn1 = log(sin (x+3))^5 == 8 ;
> let sol1 = simplify $ solve eqn1 x;

The variable sol1 now contains an entire list of solutions. How many are there?
The first one is:

\[
x = 2 \cdot n \cdot \pi + \arcsin\left(\frac{e^{2^{\frac{3}{5}} \cdot \cos\left(\frac{2 \cdot \pi}{5}\right)}}{e^{2^{\frac{3}{5}} \cdot \sin\left(\frac{2 \cdot \pi}{5}\right) \cdot i}}\right) - 3
\]

where \( n \) is an arbitrary integer constant (shown as \( \text{arbint 5} \) in the result of \( \text{simplify} \)).

It is also possible to obtain the right-hand side of any solution in the list via REDUCE commands:

\[
> \text{simplify } \text{rhs } \text{first } \text{solve eqn1 x};
2 \cdot \text{arbint 10} \cdot \pi + \arcsin\left(\frac{e^{2^{\frac{3}{5}} \cdot \cos\left(\frac{2 \cdot \pi}{5}\right)}}{e^{2^{\frac{3}{5}} \cdot \sin\left(\frac{2 \cdot \pi}{5}\right) \cdot i}}\right) - 3
\]

where \( \text{first} \) gets the first solution in the list and \( \text{rhs} \) obtains the right-hand side. Hence there is a wealth of possibilities to process the solution list.

Example 2:

Here are some simpler examples for the sake of clarity:

\[X^2 + 1 = 0\]

\[
> \text{simplify } \text{solve } [X^2+1==0] X;
[X==i, X==-i]
\]

\[(x + 3y = 7) \land (y - x = 1)\]

\[
> \text{simplify } \text{solve } [x+3*y==7, y-x==1] [x, y];
[[x==1, y==2]]
\]

To get the multiplicities, turn on the switch \( \text{multiplicities} \):

\[
> \text{simplify } \text{solve } [x^2==2*x-1] x;
[x==1]
> \text{reduce::switch } "\text{multiplicities}" 1;
\]

21.6.5 Solving
> simplify $ solve [x^2==2*x-1] x;
[x==1,x==1]

For details consult the REDUCE user manual.

### 21.6.6 Even and Odd Operators

An operator can be declared to be even or odd in its first argument by the declarations \textsc{EVEN} and \textsc{ODD} respectively.

\begin{verbatim}
> declare operator [f1,f2];
[]
> declare odd f1;
[]
> declare even f2;
[]
> simplify $ f1(-a);
-f1 a
> simplify $ f2 (-a);
f2 a
> simplify $ f1 (-a) (-b);
-f1 a (-b)
\end{verbatim}

### 21.6.7 Linear Operators

An operator can be declared to be linear in its first argument over powers of its second argument.

\begin{equation}
L(a x^5 + b x + c, x) = L(x^5, x) \cdot a + L(x, x) \cdot b + L(1, x) \cdot c
\end{equation}

\begin{verbatim}
> declare operator L;
[]
> declare linear L;
[]
> simplify $ L (a*x^5+b*x+c) x ;
L (x^5) x*a+L x x*b+L 1 x*c
\end{verbatim}

\begin{equation}
L(a + b + c + d, y) = L(1, y) \cdot (a + b + c + d)
\end{equation}
> simplify $ L (a+b+c+d) y$
L 1 y*a+L 1 y*b+L 1 y*c+L 1 y*d

Note that $L x y$ binds stronger than (*) in Pure.

### 21.6.8 Non-commuting Operators

An operator can be declared to be non-commutative under multiplication by the declaration NONCOM.

> declare operator [u,v];
[]
> simplify (u(x)*u(y)-u(y)*u(x));
0
> declare noncom [u,v];
[]
> simplify (u(x)*u(y)-u(y)*u(x));
u x*u y-u y*u x

### 21.6.9 Symmetric and Antisymmetric Operators

An operator can be declared to be symmetric with respect to its arguments by the declaration SYMMETRIC. Similarly, the declaration ANTISYMMETRIC declares an operator antisymmetric.

> declare operator [A,S];
[]
> declare symmetric S;
[]
> declare antisymmetric A;
[]

> simplify $ A x x $ ;
0

> simplify $ (A x y z) + (A x z y) ;$
0

> simplify $ S y x $ ;
S x y

> simplify $ A y x $ ;
-A x y

### 21.6.10 Creating/Removing Variable Dependencies

There are several facilities in REDUCE, such as the differentiation operator and the linear operator facility, which can utilize knowledge of the dependencies between various variables. Such dependencies may be expressed by the command DEPEND.
> declare operator D ;
[]
> declare depend [D,x,y];
[]

> simplify $ df D a;
0

D does not depend on a, thus differentiating with respect to a yields 0, but

> simplify $ df D x;
df D x

because D is declared to depend on x. If we also let a depend on x, then:

> declare depend [a,x];
[]
> simplify $ df (D+a) x;
df D x+a+df a x+D

Note: Dependencies remain active until they are explicitly removed:

> declare nodepend [a,x];
> simplify $ df a x;
0
> simplify $ df (D+a) x;
df D x*a

21.6.11 Internal Order of Variables

It is possible for the user to change the internal order of variables by means of the declaration KORDER. The syntax for this is:

declare korder [v1,...,vn]

Unlike the ORDER declaration, which has a purely cosmetic effect on the way results are printed, the use of KORDER can have a significant effect on computation time.

> declare korder [z,y,x];
[]
> x+y+z;
x+y+z
> simplify $ x+y+z;
z+y+x

21.6.12 Parts of Algebraic Expressions

The following operators can be used to obtain a specific part of an expression, or even change such a part to another expression.

coeff expr::polynomial var
coeffn expr::polynomial var n::int
part expr::algebraic [n::int]
Examples:

\[ \text{coef} ((y^2+z)^3/z) y; \]
\[ [z^2, 0, 3z, 0, 3, 0, 1/z] \]

\[ \text{coeft} ((y^2+z)^3/z) y 6; \]
\[ 1/z \]

\[ \text{part} (a+b) 2; \]
\[ b \]

\[ \text{part} (a+b) 1; \]
\[ a \]

\[ \text{part} (a+b) 0; \]
\[ (+) \]

**PART** may also be used to substitute a given part of an expression. In this case, the **PART**
construct appears on the left-hand side of an assignment statement (cf. **Assignment**), and
the expression to replace the given part on the right-hand side.

\[ \text{xx} := a+b; \]
\[ a+b \]

\[ \text{part} \ xx \ 2 := c; \]
\[ c \]

\[ \text{xx}; \]
\[ a+c \]

### 21.6.13 Polynomials and Rationals

REDUCE is capable of factorizing univariate and multivariate polynomials with integer co-
efficients, finding all factors with integer coefficients. The package for doing this was written
by Dr. Arthur C. Norman and Ms. P. Mary Ann Moore at The University of Cambridge. It is
described in [SYMSAC81].

**factorize expr::polynomial** [p::prime]

Some examples:

\[ \text{factorize} (x^{105}-1) ; \]
\[ [[x^{48}+x^{47}+x^{46}-x^{43}-x^{42}-2*x^{41}-x^{40} ... ] \]

\[ \text{factorize} (12*x^2 - 12) ; \]
\[ [[2,2],[3,1],[x+1,1],[x-1,1]] \]

The following operators should be well known:

**gcd expr1::polynomial expr2::polynomial -> polynomial**

**lcm expr1::polynomial expr2::polynomial -> polynomial**
remainder expr1::polynomial expr2::polynomial -> polynomial
resultant expr1::polynomial expr2::polynomial var -> polynomial
decompose expr::polynomial -> list
interpol <values> <variable> <points>) -> polynomial
deg expr::polynomial var -> int
den expr::rational -> polynomial
lcof expr::polynomial var -> polynomial
lpower expr::polynomial var -> polynomial
lterm expr::polynomial var -> polynomial
mainvar expr::polynomial -> expr
num expr::rational -> polynomial
reduct expr::polynomial var -> polynomial

Some examples of each operator:

GCD/LCM

> simplify $ gcd (x^2+2*x+1) (x^2+3*x+2) ;
x+1
> simplify $ gcd (2*x^2-2*y^2) (4*x+4*y) ;
2*x+2*y
> simplify $ gcd (x^2+y^2) (x-y) ;
1

> simplify $ lcm (x^2+2*x+1) (x^2+3*x+2) ;
x^3+4*x^2+5*x+2
> simplify $ lcm (2*x^2-2*y^2) (4*x+4*y) ;
4*x^2-4*y^2

REMAINDER/RESULTANT

> simplify $ remainder ((x+y)*(x+2*y)) (x+3*y) ;
2*y^2
> simplify $ remainder (2*x+y) 2 ;
y
> simplify $ resultant (x/r*u+y) (u*y) u ;
-y^2

DECOMPOSE

> simplify $ decompose (x^8+88*x^7+2924*x^6-643912*x^5+263431*x^4-
218900*x^3+65690*x^2-7700*x+234) ;
[u^2+35*u+234,u==v^2+10*v,v==x^2-22*x]

> simplify $ decompose (u^2+v^2+2*u*v+1) ;
[w^2+1,w==u+v]

DEG/DEN

> simplify $ deg ((a+b)*(c+2*d)^2) d ;
2
> simplify $ deg ((x+b)*(x^6+2*y)^2) x ;
13

> simplify $ den (x/y^2) ;
y^2

LCOF/LPOWER/LTERM

> simplify $ lcof ((a+b)*(c+2*d)^2) a ;
c^2+4*c+d+4*d^2
> simplify $ lcof ((a+b)*(c+2*d)^2) d ;
4*a+4*b
> simplify $ lcof ((a+b)*(c+2*d)) ('e) ;
a+c+2*a+d+b+c+2*b+d

> simplify $ lpower ((a+b)*(c+2*d)^2) a ;
a
> simplify $ lpower ((a+b)*(c+2*d)^2) d ;
d^2
> simplify $ lpower ((a+b)*(c+2*d)) x ;
1

> simplify $ lterm ((a+b)*(c+2*d)^2) a ;
a*c^2+4*a*c+d+4*a*d^2
> simplify $ lterm ((a+b)*(c+2*d)^2) d ;
4*a*d^2+4*b*d^2
> simplify $ lterm ((a+b)*(c+2*d)) x ;
a*c+2*a*d+b*c+2*b*d

MAINVAR/NUM/REDUCT

> simplify $ mainvar ((a+b)*(c+2*d)^2) ;
a
> simplify $ mainvar 2 ;
0

> simplify $ num (x/y^2) ;
x
> simplify $ num ('(100/6)) ;
50
> simplify $ num (a/4+b/6) ;
3*a+2*b

> simplify $ reduct ((a+b)*(c+2*d)) a ;
b+c+2*b+d
> simplify $ reduct ((a+b)*(c+2*d)) d ;
a+c+b+c
> simplify $ reduct ((a+b)*(c+2*d)) x ;
0

21.6.13 Polynomials and Rationals
21.6.14 Substitution

An important class of commands in REDUCE define substitutions for variables and expressions to be made during the evaluation of expressions. One such operation is the prefix operator SUB.

\[ \text{sub} \langle \text{substlist} \rangle \text{ exprn::algebraic } \rightarrow \text{ algebraic} \]

\[
> \text{simplify} \$ \text{sub} [x==a+y, y==y+1] (x^2+y^2) ;
\]
\[
a^2+2*a*y+2*y^2+2*y+1
\]

\[
> \text{simplify} \$ \text{sub} [a==\sin x, b==\sin y] (a^2+b^2) ;
\]
\[
\sin x^2+\sin y^2
\]

Note that simple substitutions of this kind can also be done directly in Pure, using the reduce macro.

21.6.15 Assignment

One may assign values to variables in the REDUCE environment. Note that in Pure the set operator and := are equivalent, i.e. both sides are evaluated, contrary to the := version in REDUCE.

\[ \text{set} \text{ expr } \text{ expr} \]
\[ \text{expr} := \text{ expr} \]

\[
> \text{simplify} \$ \text{P} := a*x^n + b* x^m + c ;
\]
\[
// P:=a*x^n + b* x^m + c;
\]
\[
x^m*b+x^n*a+c
\]

\[
> \text{simplify} \ P ;
\]
\[
// return P (from Reduce)
\]
\[
x^m*b+x^n*a+c
\]

\[
> \text{simplify} \$ \text{df} \ P \ x ;
\]
\[
// diff P x
\]
\[
(x^m*b*m+x^n*a*n)/x
\]

\[
> \text{simplify} \$ \text{Q} := \text{intg} \ P \ x ;
\]
\[
// integrate P x, store in Q
\]
\[
(x^m*b+n*x+x^m*b+x^m*a+x^n*a+x+c+m*x+c*n+x+c+x)/(m*n+m+n+1)
\]

\[
> \text{simplify} \$ \text{set} \ Q (a*x^n + b* x^m + c) ;
\]
\[
x^m*b+x^n*a+c
\]

21.6.16 Matrix Calculations

A very powerful feature of REDUCE is the ease with which matrix calculations can be performed. It fits very well into Pure’s native matrix type.

To keep it simple we show the usage of the different operators by examples using the well known Pauli matrices. See, e.g., http://en.wikipedia.org/wiki/Pauli_matrices for a reference.

\[
\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}
\]
let \( s_0 = \{1,0;0,1\} \);
let \( s_1 = \{0,1;1,0\} \);
let \( s_2 = \{0,-i;i,0\} \);
let \( s_3 = \{1,0;0,-1\} \);

Check the identities

\[
\sigma_1^2 = \sigma_2^2 = \sigma_3^2 = -i \sigma_1 \sigma_2 \sigma_3 = \sigma_0
\]

where \( \sigma_0 \) denotes the unit matrix.

Note: Instead of \( s_1 \ast s_1 \) we could also write \( s_1^2 \) here.

\[
> \text{let } r1 = \text{simplify } (s1 \ast s1); r1; \\
> \{1,0;0,1\}
\]

\[
> \text{let } r2 = \text{simplify } (s2 \ast s2); r2; \ \\
> \{1,0;0,1\}
\]

\[
> \text{let } r3 = \text{simplify } (s3 \ast s3); r3; \ \\
> \{1,0;0,1\}
\]

\[
> \text{let } r4 = \text{simplify } (-i \ast s1 \ast s2 \ast s3); r4; \ \\
> \{1,0;0,1\}
\]

\[
> \text{let } r5 = \text{all } \{=s0\} [r1,r2,r3,r4]; r5; \ \\
> 1
\]

Check: \( \text{det } \sigma_i = -1, \forall i \in \{1,2,3\} \).

\[
> \text{map } \{\text{simplify } . \text{det}\} [s1,s2,s3]; \ \\
> [-1,-1,-1]
\]

Calculate the eigenvalues/-vectors of \( \sigma_2 \):

\[
> \text{let } r7 = \text{simplify } \text{mateigen } s2 \ q; r7; \\
> [[q-1,1],[q+1,1],[c1*i,c2]]
\]

\[
> \text{let } r8 = \text{map head } r7; r8; \ \text{// } [-q-1,q+1] \rightarrow \text{Eigenvalues } q=+/\cdot-1 \\
> [q-1,q+1]
\]

\[
> \text{let } r9 = \text{map } \{\text{head.tail}\} r7 ; r9; \ \text{// multiplicities} \\
> [1,1]
\]

\[
> \text{let } r10 = \text{map last } r7 ; r10; \ \text{// eigenvectors} \\
> [[c1*i,c2],[c3*i,c4]]
\]

Transpose (operator \( tp \)):

\[
> \text{map } \{\text{simplify}.\text{tp}\} [s1,s2,s3]; \ \text{// } [s1',s2',s3'] \\
> [[0,1,0],[0,i;0,-i],[1,0;0,-1]]
\]

Trace (operator \( \text{trace} \)):

\[
> \text{map } \{\text{simplify}.\text{trace}\} [s1,s2,s3] ; \\
> [0,0,0]
\]
Cofactor (trivial here):

\[ \text{simplify } \text{cofactor } s2 \ 1\ 1 \ ; \ 0 \]

Nullspace of \( s_2 + \{0;i;0,0\} \):

\[ \text{simplify } \text{nullspace } (s2+\{0,i;0,0\}) \ ; \ \{0;1\} \]

Rank:

\[ \text{map } (\text{simplify } . \text{ rank}) [s0,s1,s2,s3] \ ; \ [2,2,2,2] \]

Inverse (simply \( \frac{1}{\text{matrix}} \)):

\[ \text{let } r15 = \text{simplify } \frac{1}{s2} \ ; \ r15; \]

\[ \{0,1/i;(-1)/i,0\} \]

\[ \text{simplify } s2*r15 \ ; \ \{1,0;0,1\} \]

Solving without solve:

\[ \begin{align*}
a_{11} x_1 + a_{12} x_2 &= y_1 \\
a_{21} x_1 + a_{22} x_2 &= y_2
\end{align*} \]

\[ \text{simplify } (1/\{a11,a12;a21,a22\} \cdot \{y1;y2\}) \ ; / / A^-1 \cdot y' ; \]

\[ \{-a12 \cdot y2 + a22 \cdot y1\}/(a11 \cdot a22 - a12 \cdot a21); \{a11 \cdot y2 - a21 \cdot y1\}/(a11 \cdot a22 - a12 \cdot a21) \]

21.6.17 Limits

From the package description:

LIMITS is a fast limit package for REDUCE for functions which are continuous except for computable poles and singularities, based on some earlier work by Ian Cohen and John P. Fitch. This package defines a LIMIT operator, called with the syntax:

\[ \text{limit expr::alg var limpoint::alg -> alg} \]

\[ \lim_{x \to \infty} x \sin \frac{1}{x} = ?, \ \lim_{x \to 0} \frac{1}{x} = ? \]
> simplify $ limit (x*sin(1/x)) x infinity ;
1

> simplify $ limit (1/x) x 0 ;
inf

Notes: This package loads automatically. Author: Stanley L. Kameny.

### 21.6.18 Ordinary differential equations solver

The ODESOLVE package is a solver for ordinary differential equations.

**Problem 1:**
\[
\frac{dy}{dx} = x^2 + e^x
\]

> declare depend [y,x]; // declare: y depends on x
[[]]

> simplify $ odesolve [df y x == x^2+exp(x)] [y] x ;
[y==(3*C+3*e^x+x^3)/3]

**Problem 2:**
\[
\frac{d^2 y}{dx^2} = y(x) \land y(0) = A \land y(1) = B
\]

> simplify $ odesolve [(df y x 2) == y] [y] x \[[x==0,y==A],[x==1,y==B]] ;
[y==(-e^(2*x)*A+e^(2*x)*B*e+A*e^2-B*e)/(e^x*e^2-e^x)]

Remember to remove dependencies:
> declare nodepend [y,x];
[[]]

### 21.6.19 Series Summation and Products

**SUM**: A package for series summation

From the package description:

The package implements the Gosper algorithm for the summation of series. It defines operators SUM and PROD. The operator SUM returns the indefinite or definite summation of a given expression, and PROD returns the product of the given expression. This package loads automatically. Author: Fujio Kako.
Calculate

\[
\sum_{n=1}^{N} n^3, \quad \sum_{k=0}^{n-1} (a + kr), \quad \sum_{k=1}^{n+1} \frac{1}{(p + (k - 1)q) \cdot (p + kq)}, \quad \prod_{k=1}^{N} k + 2
\]

> simplify $ \text{sum} (n^3) n 1 N ;$

\[(N^4+2*N^3+N^2)/4\]

> simplify $ \text{sum} (a+k*r) k 0 (n-1) ;$

\[(2*a+n+n^2+r-n*r)/2\]

> simplify $ \text{sum} (1/((p+(k-1)*q)+(p+k*q))) k 1 (n+1) ;$

\[(n+1)/(n*p+q+p^2+p*q)\]

> simplify $ \text{prod} (k/(k+2)) k 1 N ;$

\[2/(N^2+3*N+2)\]

### 21.6.20 Taylor Series

**TAYLOR:** Manipulation of Taylor series

From the package description:

This package carries out the Taylor expansion of an expression in one or more variables and efficient manipulation of the resulting Taylor series. Capabilities include basic operations (addition, subtraction, multiplication and division) and also application of certain algebraic and transcendental functions. Author: Rainer Schöpf.

Example:

\[e^{x^2+y^2} = 1 + y^2 + x^2 + y^2 \cdot x^2 + O(x^3,y^3)\]

For details consult the package documentation in the REDUCE distribution.

> simplify $ \text{taylor} (\exp (x^2+y^2)) x 0 2 y 0 2 ;$

\[x^2+y^2+x^2+y^2+1\]

> simplify $ \text{taylor} (\exp x) x 0 3;$

\[(x^3+3*x^2+6*x+6)/6\]

> simplify $ \text{implicit_taylor} (x^2+y^2-1) x y 0 1 5 ;$

\[(-x^4-4*x^2+8)/8\]

> simplify $ \text{inverse_taylor} (\exp(x)-1) x y 0 8;$

\[(-105*y^8+120*y^7-140*y^6+168*y^5-210*y^4+280*y^3-420*y^2+840*y)/840\]

Note that the "big O" residual terms are omitted in the results returned by `simplify`, although REDUCE will print them.
21.6.21 Boolean Expressions

The truth values within REDUCE are t and nil = (). Not all predicates (functions returning a truth value) can be called by simplify, however, so one has to use the lisp function in some circumstances.

Some examples:

```lisp
> simplify $ evenp 200 ;
t
> simplify $ evenp 201 ;
[]
```

```lisp
> lisp (fixp 200) ;
t
```

where fixp tests for integers.

The following example shows a pitfall. Since there is a numberp function in both Pure and REDUCE, the function needs to be quoted to make the expression go through to REDUCE:

```lisp
> lisp (numberp x) ;
0
> lisp (numberp 111) ;
1
```

```lisp
> lisp ('numberp x) ;
[]
> lisp ('numberp 111) ;
t
```

In the first case numberp x evaluates to zero in Pure, so the lisp function gets 0 and returns 0. In the second case (quoted) the function numberp is evaluated in REDUCE and returns nil, i.e. [] in Pure. Of course, both results are correct but there may be other cases where equally named functions have different meanings in the two environments.

Some other useful predicates in REDUCE are ordp and freeof:

```lisp
> lisp (ordp x y) ;
t
> lisp (ordp y x) ;
[]
```

```lisp
> lisp (ordp "abc" "abd") ;
t
> lisp (ordp "abd" "abc") ;
[]
> lisp (ordp 3 5) ;
[]
> lisp (ordp 5 3) ;
t
```

```lisp
> simplify $ freeof (x^2+y) x ;
0
> simplify $ freeof (x^2+y) z ;
```
21.6.22 Mathematical Functions

REDUCE provides many mathematical functions which can take arbitrary scalar expressions as their single argument:

- ACOS, ACOSH, ACOT, ACOTH, ACSC, ACSCH, ASEC, ASECH, ASIN, ASINH
- ATAN, ATANH, ATAN2, COS, COSH, COT, COTH, CSC, CSCH, DILOG, EI, EXP
- HYPOT, LN, LOG, LOG10, SEC, SECH, SIN, SINH, SQRT, TAN, TANH, ERF

Note that Pure also defines some of these functions in its `math` module, so these may have to be quoted to prevent evaluation on the Pure side. For instance:

```reduce
> simplify $ cos 4.3;
cos (43/10)
> using math;
warning: external 'exp' shadows previous undefined use of this symbol
warning: external 'sin' shadows previous undefined use of this symbol
warning: external 'cos' shadows previous undefined use of this symbol
> simplify $ cos 4.3;
(-21601483)/53896027
```

Some examples:

```reduce
> simplify $ cos (-x);
cos x
> simplify $ cos (n*pi);
cos (80143857*n/25510582)
> simplify $ (quote e)^(3*i*(quote pi)/2);
-i
> simplify $ sec (quote pi);
-1
> let simplify $ log10 10;
1
> simplify $ erf (-a);
-erf a
```

The special functions are in two separate packages `SPECFN` and `SPECFN2`:

- Bernoulli Numbers and Euler Numbers;
- Stirling Numbers;
- Binomial Coefficients;
- Pochhammer notation;
- The Gamma function;
- The Psi function and its derivatives;
• The Riemann Zeta function;
• The Bessel functions J and Y of the first and second kind;
• The modified Bessel functions I and K;

21.6.23 Definite Integrals

DEFINT: Calculating definite integrals by using the Meijer G integration formula.

\[ \int_{0}^{\infty} e^{-x} \, dx \]
> reduce::load "defint" ;
0

> simplify $ intg (exp(-x)) x 0 infinity ;
1

\[ \int_{0}^{\infty} x^2 \cos(x) e^{-2x} \, dx \]

> simplify $ intg (x^2*cos(x)*exp(-2*x)) x 0 infinity ;
4/125

\[ \int_{0}^{1} x e^{-\frac{1}{2}x} \, dx \]

> simplify $ intg (x*exp(-1/2*x)) x 0 1 ;
2*sqrt e*(2*sqrt e-3)/e

\[ \int_{0}^{1} x \log(1 + x) \, dx \]

> simplify $ intg (x*log(1+x)) x 0 1 ;
1/4

\[ \int_{y}^{2y} \cos(2x) \, dx \]

> simplify $ intg (cos(2*x)) x y (2*y);
(sin (4*y)-sin (2*y))/2

Various transformations:
> simplify $ laplace_transform (exp(-a*x)) x ;
1/(a+s)

> simplify $ hankel_transform (exp(-a*x)) x ;
s^(n/2)*gamma (n/2)*hypergeometric [(n+2)/2] [n+1]
((-s)/a)*n/(2*a^(n/2)+gamma (n+1)+a)

> simplify $ y_transform (exp(-a*x)) x ;
(a^n*gamma (n+1)*gamma ((-n)/2)+gamma ((-2+n-1)/2)*gamma
((2+n+3)/2)+hypergeometric [(-n+2)/2] [-n+1] ((-s)/a)+s^n*gamma
(-n)*gamma (n/2)*hypergeometric [(n+2)/2] [n+1] ((-s)/a)*n*pi)/
(2*s^(n/2)+a^n(n/2)+gamma ((-2+n-1)/2)*gamma ((2+n+3)/2)+a*pi)

> simplify $ k_transform (exp(-a*x)) x ;
(-a^n*gamma (n+1)*gamma ((-n)/2)+hypergeometric [(-n+2)/2] [-n+1]
(s/a)+s^n*gamma (-n)*gamma (n/2)*hypergeometric [(n+2)/2] [n+1] (s/a)*n)/
(4*pi*a^(n+1)/a^n(n/2)+a)/

> simplify $ struveh_transform (exp(-a*x)) x ;
2*s^((n+1)/2)*gamma ((n+3)/2)*hypergeometric [1,(n+3)/2] [(2+n+3)/2,3/2]
((-s)/a)/(sqrt pi*a^((n+1)/2)+gamma ((2+n+3)/2)+a)

> simplify $ fourier_sin (exp(-a*x)) x ;
s/(a^2+s^2)
> simplify $ fourier_cos (exp(-a*x)) x ;
a/(a^2+s^2)

21.6.24 Declarations, Switches and Loading

Lisp evaluation can be used in the REDUCE system, in particular, to declare operator symbols and their properties (simplify won’t do that). E.g.:

> lisp ('operator [myop]);
> lisp ('flag [myop] odd);
> lisp ('prop myop); // => [odd:t,simpfn:simpiden]
> simplify (myop (-x)); // => -myop x

For the most common kinds of declarations, the reduce module provides the declare function which takes care of the necessary Lisp magic and is safe to use. The above example can also be done as follows:

> declare operator myop;
> declare odd myop;
> simplify (myop (-x));
- -myop x

Please see the description of declare for a list of supported declarations.

The reduce module also provides a few other basic maintenance functions which are done with special commands in REDUCE:

reduce::switch "switch-name" 0|1
reduce::load "package-name"
reduce::in "path/filename.red"
reduce::capture 0|1
reduce::feed "text"

As already mentioned, REDUCE switches can be turned on and off with reduce::switch, e.g.:

> reduce::switch "exp" 0 ;
0

Packages can be loaded with the reduce::load command:

> reduce::load "defint" ;
0

REDUCE source files can be read in with the reduce::in command:

> reduce::in "myreduce.red" ;
0

Last but not least, REDUCE terminal input and output can also be redirected to string buffers using the reduce::feed and reduce::capture functions. For instance, the following code feeds some text with a Lisp form to REDUCE, which gets read by evaluating the Lisp form (eval read). The output is captured and can be inspected with the reduce::output function:

> reduce::feed "(print '(a b c d))";
0
> reduce::capture 1; // start capturing output
0
> lisp ('eval read); // read buffered input and evaluate [a,b,c,d]
> reduce::output; // inspect buffered output
"(a b c d)\n"
> reduce::capture 0; // stop capturing output
0

21.6.25 Plotting

REDUCE can do 2- and 3-dimensional function plots through its gnuplot package. Some examples (note that we have to quote the x..y ranges here so that they get through to Reduce, rather than being evaluated on the Pure side):

> simplify $ plot (sin x/x) (x=='(-15..15));

// Multiple ranges.
> simplify $ plot (sin(x^2 + y^2) / sqrt(x^2 + y^2)) [x=='(-12..12), y=='(-12..12)];

// Specifying options.
> simplify $ plot (cos (sqrt(x^2 + y^2))) [x=='(-3..3),y=='(-3 .. 3)] hidden3d;
// Specifying points.
> simplify $ plot [[0,0],[0,1],[1,1],[0,0],[1,0],[0,1],[0.5,1.5],[1,1],[1,0]]; 

// Output options.
> simplify $ plot (sin x) [x=='(0..10),terminal==postscript,output=="sin.ps"];

Pure-CSV - Comma Separated Value Interface for the Pure Programming Language

Version 1.6, April 11, 2018

Eddie Rucker <erucker@bmc.edu>

The CSV library provides an interface for reading and writing comma separated value files. The module is very loosely based on Python’s CSV module (http://docs.python.org/lib/module-csv.html).

22.1 Installation

Run make to compile the module and make install (as root) to install it in the Pure library directory. This requires GNU make. The make install step is only necessary for system-wide installation.

The make utility tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, make install prefix=/usr sets the installation prefix, and make PIC=-fPIC or some similar flag might be needed for compilation on 64 bit systems. Please see the Makefile for details.

22.2 Usage

Data records are represented as vectors or lists of any Pure values. Values are converted as necessary and written as a group of strings, integers, or doubles separated by a delimiter. Three predefined dialects are provided; DEFAULT (record terminator= \n ), RFC4180 (record terminator= \r\n ), and Excel. Procedures are provided to create other CSV dialects. See (http://www.ietf.org/rfc/rfc4180.txt) for more details about the RFC4180 standard.
22.2.1 Handling Errors

**error** msg is an error handling term. Operations resulting in parse errors, memory errors, or read/write errors produce a special csv::error msg term, where msg is a string describing the particular error. Your application should either check for these or have csv::error defined to directly handle errors in some way (e.g., provide a default value, or raise an exception).

22.2.2 Creating Dialects

dialect record creates a dialect from a record of dialect option pairs. The dialect object is freed automatically when exiting the pure script. The list of possible options and option values are presented below:

- **delimiter** - Character used to separate fields.
  - Value - any string.
  - Default - ",".

- **escape** - Embedded escape character used to embed a delimiter, escape, or terminator into unquoted fields. If the escape character is not null, then the quote character is ignored.
  - Value - any string.
  - Default - "".
  - Reading - The escape character is dropped and the next char is inserted into the field.
  - Writing - The escape character is written into the output stream before the delimiter, escape, or return character.

- **quote** - Quotes are used to embed delimiters, quotes, or terminators into a field.
  - Value - any string.
  - Default - "\"".
  - Notes - Embedded quotes are doubled. The escape option must be the null string.

- **terminator** - Record termination string.
  - Value - any string.
  - Reading - Either a user specified string or if not specivied the file is sniffed for a \r, \r\n, or \n.
  - Writing - Either a user specified string, \r\n for Windows platforms, or \n for everything else.

- **quote_flag** - Sets the quoting style of strings and/or numbers.
  - Value - One of {ALL, STRINGS, MINIMAL}.
– Default - ALL.

– Reading -
  1. ALL - Every field is read as a string.
  2. STRING, MINIMAL - Fields within quotes and fields that cannot be converted to integers or doubles are read as strings.

– Writing -
  1. ALL - Every field is written within quotes.
  2. STRING - Only fields of type string are quoted.
  3. MINIMAL - Only fields containing embedded quotes, terminators, or delimiters are written within quotes.

• space_around_quoted_field - Determines how white space between quotes and delimiters should be treated.
  – Value - One of {NO, LEFT, RIGHT, BOTH}.
  – Default - NO.

– Reading -
  1. NO - Follows RFC4180 rules.
  2. LEFT - Allows space before a quoted field.
  3. RIGHT - Allows space between a quoted field and a delimiter.
  4. BOTH - Allows space before and after a quoted field.

– Writing - fields are never written with space before a quoted field or between a quoted field and a delimiter.

– Notes this option does not affect space within quotes or fields written using the escape string option.

• trim_space - trim white space before or after field contents.
  – Value - One of {NO, LEFT, RIGHT, BOTH}.
  – Default - NO.

– Reading -
  1. NO - Reading follows RFC4180 rules.
  2. LEFT, RIGHT, or BOTH - The field is trimmed accordingly. Use caution because trimming may allow automatic conversion of numbers if the quote_flag is set to MINIMAL.

– Writing -
  1. NO - Reading follows RFC4180 rules
2. LEFT, RIGHT, or BOTH - Trimming space is probably a bad idea since leading or trailing space may be significant for other applications.

The following example illustrates the construction of a dialect for reading tab delimited files without quoted strings.

Example

```>
using csv;
> using namespace csv;
> let d = dialect {delimiter=>"\t", quote_flag=>STRING};
```

### 22.2.3 Opening CSV Files

**open name::string** opens a CSV file for reading using the default dialect. If the file does not exist, the error msg rule is invoked.

**open (name::string, rw_flag::string)** opens a CSV file for reading, writing, or appending using the default dialect. Valid rw_flag values are "r" for reading, "w" for writing, and "a" for appending. If the file does not exist when opened for reading, the error msg rule is invoked. When a file is opened for writing and the file exists, the old file is overwritten. If the file does not exist, a new empty file is created. When a file is opened for appending and the file exists, new records are appended to the end of the file, otherwise a new empty file is created.

**open (name::string, rw_flag::string, d::matrix)** exactly as above except reading/writing is done according to a user defined dialect d.

**open (name::string, rw_flag::string, d::matrix, opts@(_:_))** exactly as above except allows for list output or header options when reading.

1. If opts contains LIST, the output of getr, fgetr, and fgetr_lazy is a list instead of a vector.

2. If opts contains HEADER, the first line of the file is automatically read and parsed as a record where entries are key=>position pairs where key is a string and position is an integer denoting the location of a field within the record. The header record may be accessed by header.

Examples

```>
using csv;
> using namespace csv;
> let d = dialect {delimiter=>"\t"};
> let f = open ("junk.csv", "w", d);
> putr f{"hello",123,"",3+:4,world};
> close f;
```

```>
let f = open ("junk.csv", "r", d);
> getr f;
```
Suppose our file “test.csv” is as presented below.

```
ir$ more test.csv
NAME,TEST1,TEST2
"HOPE, BOB",90,95
"JONES, SALLY",88,72
"RED, FEEFEE",45,52
```

Notice how the LIST option affects the return of `getr` and how the HEADER option may be used to index records.

```
> using csv;
> using namespace csv;
> let d = dialect {quote_flag=>MINIMAL};
> let f = open ("test.csv", "r", d, [LIST,HEADER]);
> let r = getr f;
> r!0;
"HOPE, BOB"
> let k = header f;
> k;
{"NAME"=>0,"TEST1"=>1,"TEST2"=>2}
> r!(k!"NAME");
"HOPE, BOB"
> r!!(k!!["NAME","TEST1"]);
["HOPE, BOB",90]
>
```

### 22.2.4 File Reading Functions

- **header** `csv_file::pointer` returns the record of key=>position pairs when opened by `csv::open` using the header option. If the file was opened without the HEADER option, `{}` is returned.

- **getr** `csv_file::pointer` reads from a `csv_file` opened by `csv::open` and returns a record represented as a row matrix. Reading from a file opened for writing or appending invokes the `error msg` rule.

- **fgetr** `csv_file::pointer` reads a whole file and returns a list of records. This procedure should only be used on data files that are small enough to fit in the computer’s primary memory. Reading from a file opened for writing or appending invokes the `error msg` rule.

- **fgetr_lazy** `csv_file::pointer` Lazy version of `fgetr`.

### 22.2.5 File Writing Functions

When modifying CSV files that will be imported into Microsoft Excel, fields with significant leading 0s should be written using a `"=""0...""` formatting scheme. This same technique
will work for preserving leading space too. Again, this quirk should only be necessary for files to be imported into MS Excel.

**putr csv_file::pointer rec::matrix** writes a record in row matrix format to csv_file.
Writing to a file opened for reading invokes the error msg rule.

**fputr csv_file::pointer l@(_:_)** writes a list of records where each record is a row matrix to csv_file. Writing to a file opened for reading invokes the error msg rule.

### 22.2.6 Examples

The first example shows how to write and read a default CSV file.

```bash
> using csv;
> using namespace csv;
> let f = open ("testing.csv", "w");
> fputr f [{"bob",3.9,"",-2},{"fred",-11.8,"",0},{"mary",2.3,"$",11}];
> close f;
> let f = open "testing.csv";
> fgetr f;
[{{"bob","3.9","",-2},{"fred","-11.8","",0},{"mary","2.3","$",11}}
> close f;
>
```

The second example illustrates how to write and read a CSV file using automatic conversions.

```bash
> using csv;
> using namespace csv;
> let d = dialect {quote_flag=>MINIMAL};
> let f = open ("test.csv", "w", d);
> putr f {"I","",-4,1.2,2%4,like};
> close f;
> putr f {"playing","the",0,-0.2,1+:4,drums};
> close f;
> let f = open ("test.csv", "r", d);
> fgetr f;
[{{"I","",-4,1.2,2%4,"like"},{"playing","the",0,-0.2,"1+:4","drums"}}
> close f;
>
```

Records containing quotes, delimiters, and line breaks are also properly handled.

```bash
> using csv;
> using namespace csv;
> let d = dialect {quote_flag=>STRING};
> let f = open ("test.csv", "w", d);
> fputr f [{"this\nisisn",1},{"a \"test\"",2}];
```
Consider the following handwritten CSV file. According to RFC4180, this is not a valid CSV file. However, by using the `space_around_quoted_field`, the file can still be read.

```
erucker:$ more test.csv
"this", "is", "not", "valid"
```

The `trim_space` flag should be used with caution. A field with space in front of a number should be interpreted as a string, but consider the following file.

```
erucker:$ more test.csv
" this ", 45 ,23, hello
```

Now observe the differences for the two dialects below.

```
> using csv;
> using namespace csv;
> let d = dialect {trim_space=>BOTH};
> let f = open ("test.csv","r",d);
> getr f;
{"this","45","23","hello"}
> let d = dialect {trim_space=>BOTH, quote_flag=>MINIMAL};
> let f = open ("test.csv","r",d);
> getr f;
{"this",45,23,"hello"}
```

The `trim_space` flag also affects writing.

```
> using csv;
> using namespace csv;
> let d = dialect {trim_space=>BOTH};
> let f = open ("test.csv","w",d);
```
> putr f { "this", 45 }; ()
> close f; ()
> quit

erucker:$ more test.csv
"this","45"

For the last example a tab delimiter is used, automatic conversions is on, and records are represented as lists. Files are automatically closed when the script is finished.

> using csv;
> using namespace csv;
> let d = dialect {quote_flag=>MINIMAL, delimiter=>"\t"};
> let f = open ("test.csv", "w", d, [LIST]);
> fputr f [ ["a","b","-4.5",""], ["c","d",2.3,"-" ] ]; ()
> close f; ()
> let f = open ("test.csv", "r", d, [LIST]);
> fgetr f;
[ ["a","b","-4.5",""], ["c","d",2.3,"-" ] ]
> quit
pure-fastcgi: FastCGI module for Pure

Version 0.6, April 11, 2018
Albert Gräf <aggraef@gmail.com>

This module lets you write FastCGI scripts with Pure, to be run by web servers like Apache. Compared to normal CGI scripts, this has the advantage that the script keeps running and may process as many requests from the web server as you like, in order to reduce startup times and enable caching techniques. Most ordinary CGI scripts can be converted to use FastCGI with minimal changes.

23.1 Copying

Copyright (c) 2009 by Albert Graef. pure-fastcgi is distributed under a 3-clause BSD-style license, please see the included COPYING file for details.

23.2 Installation

Besides Pure, you’ll need to have the FastCGI library installed to compile this module. Also, to run FastCGI scripts, your web server must be configured accordingly; see the documentation of FastCGI and your web server for details.

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-fastcgi-0.6.tar.gz.

Running make compiles the module, make install installs it in your Pure library directory. You might have to adjust the path to the fcgi_stdio.h header file in fastcgi.c and/or the option to link in the FastCGI library in the Makefile.

The Makefile tries to guess the host system type and Pure version, and set up some platform-specific things accordingly. If this doesn’t work for your system then you’ll have to edit the Makefile accordingly.
23.3 Usage

pure-fastcgi provides the `accept` function with which you tell the FastCGI server that your script is ready to accept another request.

```c
fastcgi::accept
    Accept a FastCGI request.
```

The module also overrides a number of standard I/O functions so that they talk to the server instead. These routines are all in the `fastcgi` namespace. In your Pure script, you can set up a simple loop to process requests as follows:

```bash
#!/usr/local/bin/pure -x

using fastcgi;
using namespace fastcgi;

extern char *getenv(char *);

main count = main count when
    count = count + 1;
    printf "Content-type: text/html\n\n<title>FastCGI Hello! (Pure, fcgi_stdio library)</title>\n<h1>FastCGI Hello! (Pure, fcgi_stdio library)</h1>\nRequest number %d running on host \<i>%s</\i>\n" (count, getenv "SERVER_NAME");
end if accept >= 0;

main 0;
```

(You might have to adjust the “shebang” in the first line above, so that the shell finds the Pure interpreter. Also, remember to make the script executable. If you’re worried about startup times, or if your operating system doesn’t support shebangs, then you can also use the Pure interpreter to compile the script to a native executable instead.)

This script keeps running until `accept` returns -1 to indicate that the script should exit. Each call to `accept` blocks until either a request is available or the FastCGI server detects an error or other kind of termination condition. As with ordinary CGI, additional information about the request is available through various environment variables. A list of commonly supported environment variables and their meaning can be found in The Common Gateway Interface specification.

A number of other routines are provided to deal with data filters, finish a request and set an exit status for a request. These correspond to operations provided by the FastCGI library, see the FastCGI documentation and the `FCGI_Accept(3)`, `FCGI_StartFilterData(3)`, `FCGI_Finish(3)` and `FCGI_SetExitStatus(3)` manpages for details. An interface to the `FCGI_ToFILE` macro is also available. Note that in Pure these functions are called `accept`, `start_filter_data`, `finish`, `set_exit_status` and `to_file`, respectively, and are all declared in the `fastcgi` namespace. A detailed listing of all routines can be found in the `fastcgi.pure` module.

Please see the examples subdirectory in the pure-fastcgi sources for some more elaborate
examples.

Note that to run your FastCGI scripts in a browser, your web server must have the FastCGI module loaded and must also be set up to execute the scripts. E.g., when using Apache, the following configuration file entry will set up a directory for FastCGI scripts:

```plaintext
ScriptAlias /fastcgi-bin/ " /srv/www/fastcgi-bin/
<Location /fastcgi-bin/>
  Options ExecCGI
  SetHandler fastcgi-script
  Order allow,deny
  Allow from all
</Location>
```

(Replace fastcgi-script with fcgid-script if you’re running mod_fcgid rather than mod_fastcgi.)

Put this entry into http.conf or a similar file provided by your Apache installation (usually under /etc/apache2), and restart Apache. After that you can just throw your scripts into the fastcgi-bin directory to have them executed via an URL like http://localhost/fastcgi-bin/myscript.

You can also set up a handler for the .pure filename extension as follows:

```plaintext
<IfModule mod_fastcgi.c>
  <FilesMatch "\.pure$">
    AddHandler fastcgi-script .pure
    Options +ExecCGI
  </FilesMatch>
</IfModule>
```

(Again, you’ll have to adjust the IfModule statement and replace fastcgi-script with fcgid-script if you’re running mod_fcgid.) After that you should be able to execute scripts with the proper extension anywhere under your server’s document root.

23.3 Usage
Chapter 24

Pure-ODBC - ODBC interface for the Pure programming language

Version 0.10, April 11, 2018

Albert Graef <aggraef@gmail.com>
Jiri Spitz <jiri.spitz@bluetone.cz>

This module provides a simple ODBC interface for the Pure programming language, which lets you access a large variety of open source and commercial database systems from Pure. ODBC a.k.a. “Open Database Connectivity” was originally developed by Microsoft for Windows, but is now available on many different platforms, and two open source implementations exist for Unix-like systems: iODBC (http://www.iodbc.org) and unixODBC (http://www.unixodbc.org).

ODBC has become the industry standard for portable and vendor independent database access. Most modern relational databases provide an ODBC interface so that they can be used with this module. This includes the popular open source DBMSs MySQL (http://www.mysql.com) and PostgreSQL (http://www.postgresql.org). The module provides the necessary operations to connect to an ODBC data source and retrieve or modify data using SQL statements.

To make this module work, you must have an ODBC installation on your system, as well as the driver backend for the DBMS you want to use (and, of course, the DBMS itself). You also have to configure the DBMS as a data source for the ODBC system. On Windows this is done with the ODBC applet in the system control panel. For iODBC and unixODBC you can either edit the corresponding configuration files (/etc/odbc.ini and/or ~/.odbc.ini) by hand, or use one of the available graphical setup tools. More information about the setup process can be found on the iODBC and unixODBC websites.
24.1 Copying

Copyright (c) 2009 by Albert Graef <aggraef@gmail.com>.
Copyright (c) 2009 by Jiri Spitz <jiri.spitz@bluetone.cz>.

pure-odbc is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-odbc is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

24.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-odbc-0.10.tar.gz.

Run `make` to compile the module and `make install` (as root) to install it in the Pure library directory. This requires GNU make, and of course you need to have Pure installed. The only other dependency is the GNU Multiprecision Library (GMP).

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, `make install prefix=/usr` sets the installation prefix, and `make PIC=-fPIC` or some similar flag might be needed for compilation on 64 bit systems. The variable `ODBCLIB` specifies the ODBC library to be linked with. The default value is `ODBCLIB=-lodbc`. Please see the Makefile for details.

24.3 Opening and Closing a Data Source

To open an ODBC connection, you have to specify a “connect string” which names the data source to be used with the `odbc::connect` function. A list of available data sources can be obtained with the `odbc::sources` function. For instance, on my Linux system running MySQL and PostgreSQL it shows the following:

```
> odbc::sources;
[("myodbc","MySQL ODBC 2.50"),("psqlodbc","PostgreSQL ODBC")]
```

The first component in each entry of the list is the name of the data source, which can be used as the value of the `DSN` option in the connect string, the second component provides a short description of the data source.

Likewise, the list of ODBC drivers available on your system can be obtained with the `odbc::drivers` function which returns a list of pairs of driver names and attributes. (Older ODBC implementations on Unix lacked this feature, but it seems to be properly supported in
recent unixODBC implementations at least.) This function can be used to determine a legal value for the DRIVER attribute in the connect string, see below.

The odbc::connect function is invoked with a single parameter, the connect string, which is used to describe the data source and various other parameters such as user id and password. For instance, on my system I can connect to the local myodbc data source from above as follows:

```
> let db = odbc::connect "DSN=myodbc";
```

The odbc::connect function returns a pointer to an ODBCHandle object which is used to refer to the database connection in the other routines provided by this module. An ODBCHandle object is closed automatically when it is no longer accessible. You can also close it explicitly with a call to the odbc::disconnect function:

```
> odbc::disconnect db;
```

After odbc::disconnect has been invoked on a handle, any further operations on it will fail.

odbc::connect allows a number of attributes to be passed to the ODBC driver when opening the database connection. E.g., here’s how to specify a username and password; note that the different attributes are separated with a semicolon:

```
> let db = odbc::connect "DSN=myodbc;UID=root;PWD=guess";
```

The precise set of attributes in the connect string depends on your ODBC driver, but at least the following options should be available on most systems. (Case is insignificant in the attribute names, so e.g. the DATABASE attribute may be specified as either DATABASE, Database or database.)

- DSN=<data source name>
- DRIVER=<driver name>
- HOST=<server host name>
- DATABASE=<database path>
- UID=<user name>
- PWD=<password>

The following attributes appear to be Windows-specific:

- FILEDSN=<DSN file name>
- DBQ=<database file name>

Using the FILEDSN option you can establish a connection to a data source described in a .dsn file on Windows, as follows:

```
> odbc::connect "FILEDSN=test.dsn";
```
Usually it is also possible to directly connect to a driver and name a database file as the data source. For instance, using the MS Access ODBC driver you can connect to a database file test.mdb as follows:

\[ \text{odbc::connect "DRIVER=Microsoft Access Driver (*.mdb);DBQ=test.mdb";} \]

SQLite (http://www.sqlite.org) provides another way to get a database up and running quickly. For that you need the SQLite library and the SQLite ODBC driver available at http://www.ch-werner.de/sqliteodbc. Then you can open an SQLite database as follows (the database file is named with the DATABASE attribute and is created automatically if it doesn’t exist):

\[ \text{odbc::connect "DRIVER=SQLite3;Database=test.db";} \]

SQLite generally performs very well if you avoid some pitfalls (in particular, big batches of updates/inserts should be done within a transaction, otherwise they will take forever). It is certainly good enough for smaller databases and very easy to set up. Basically, after installing SQLite and its ODBC driver you’re ready to go immediately. This makes it a very convenient alternative if you don’t want to go through the tedium of setting up one of the big hulking DBMS.

### 24.4 Getting Information about a Data Source

You can get general information about an open database connection with the `odbc::info` function. This function returns a tuple of strings with the following items (see the description of the SQLGetInfo() function in the ODBC API reference for more information):

- **DATA_SOURCE_NAME**: the data source name
- **DATABASE_NAME**: the default database
- **DBMS_NAME**: the host DBMS name
- **DBMS_VER**: the host DBMS version
- **DRIVER_NAME**: the name of the ODBC driver
- **DRIVER_VER**: the version of the ODBC driver
- **DRIVER_ODBC_VER**: the ODBC version supported by the driver
- **ODBC_VER**: the ODBC version of the driver manager

E.g., here is what the connection to MySQL shows on my Linux system:

\[ \text{odbc::info db; \"myodbc\", \"test\", \"MySQL\", \"5.0.18\", \"myodbc3.dll\", \"03.51.12\", \"03.51\", \"03.52\";} \]

The `odbc` module also provides a number of operations to retrieve a bunch of additional meta information about the given database connection. In particular, the `odbc::getinfo` function provides a direct interface to the SQLGetInfo() routine. The result of `odbc::getinfo` is a pointer which can be converted to an integer or string value, depending on the type of information requested. For instance:
> get_short $ odbc::getinfo db odbc::SQL_MAX_TABLES_IN_SELECT; 31

> cstring_dup $ odbc::getinfo db odbc::SQL_IDENTIFIER_QUOTE_CHAR; "'

Information about supported SQL data types is available with the odbc::typeinfo routine (this returns a lot of data, see odbc.pure for an explanation):

> odbc::typeinfo db odbc::SQL_ALL_TYPES;

Moreover, information about the tables in the current database, as well as the structure of the tables and their primary and foreign keys can be retrieved with the odbc::tables, odbc::columns, odbc::primary_keys and odbc::foreign_keys functions:

> odbc::tables db; [["event","TABLE"],("pet","TABLE")]

> odbc::columns db "pet";
[["name","varchar","NO","''"],("owner","varchar","YES",odbc::SQLNULL),
("species","varchar","YES",odbc::SQLNULL),("sex","char","YES",odbc::SQLNULL),
("birth","date","YES",odbc::SQLNULL),("death","date","YES",odbc::SQLNULL)]

> odbc::primary_keys db "pet";
["name"]

> odbc::foreign_keys db "event";
["name","pet","name"]

This often provides a convenient and portable means to retrieve basic information about table structures, at least on RDBMS which properly implement the corresponding ODBC calls. Also note that while this information is also available through special system catalogs in most databases, the details of accessing these vary a lot among implementations.

### 24.5 Executing SQL Queries

As soon as a database connection has been opened, you can execute SQL queries on it using the sql function which executes a query and collects the results in a list. Note that SQL queries generally come in two different flavours: queries returning data (so-called result sets), and statements modifying the data (which have as their result the number of affected rows). The sql function returns a nonempty list of lists (where the first list denotes the column titles, and each subsequent list corresponds to a single row of the result set) in the former, and the row count in the latter case.

For instance, here is how you can select some entries from a table. (The following examples assume the sample “menagerie” tables from the MySQL documentation. The initdb function in the examples/menagerie.pure script can be used to create these tables in your default database.)
Often the third parameter of `sql`, as above, is just the empty list, indicating a parameterless query. Queries involving marked input parameters can be executed by specifying the parameter values in the third argument of the `sql` call. For instance:

```pure
> odbc::sql db "select name,species from pet where owner='Harold'" []; [["name","species"], ["Fluffy","cat"], ["Buffy","dog"]]
```

Multiple parameters are specified as a list:

```pure
> odbc::sql db "select name,species from pet where owner=?” ["Harold"]; [["name","species"], ["Fluffy","cat"], ["Buffy","dog"]]
```

Parameterized queries are particularly useful for the purpose of inserting data into a table:

```pure
> odbc::sql db "insert into pet values (?,?,?,?,?,?)" ["Puffball","Diane","hamster","f","1999-03-30",odbc::SQLNULL];
```

In this case we could also have hard-coded the data to be inserted right into the SQL statement, but a parameterized query like the one above can easily be applied to a whole collection of data rows, e.g., as follows:

```pure
> do (odbc::sql db "insert into pet values (?,?,?,?,?,?)") data;
```

Parameterized queries also let you insert data which cannot be specified easily inside an SQL query, such as long strings or binary data.

The following SQL types of result and parameter values are recognized and converted to/from the corresponding Pure types:

<table>
<thead>
<tr>
<th>SQL value/type</th>
<th>Pure value/type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL NULL (no value)</td>
<td>odbc::SQLNULL</td>
</tr>
<tr>
<td>integer types</td>
<td>int</td>
</tr>
<tr>
<td>64-bit integers</td>
<td>bigint</td>
</tr>
<tr>
<td>floating point types</td>
<td>double</td>
</tr>
<tr>
<td>binary data</td>
<td>(size, data)</td>
</tr>
<tr>
<td>character strings</td>
<td>string</td>
</tr>
</tbody>
</table>

Note the special constant (nonfix symbol) `odbc::SQLNULL` which is used to represent SQL NULL values.

Also note that binary data is specified as a pair (size, data) consisting of an int or bigint size which denotes the size of the data in bytes, and a pointer data (which must not be a null pointer unless size is 0 as well) pointing to the binary data itself.

All other SQL data (including, e.g., TIME, DATE and TIMESTAMP) is represented in Pure using its character representation, encoded as a Pure string.
Some databases also allow special types of queries (e.g., “batch” queries consisting of multiple SQL statements) which may return multiple result sets and/or row counts. The sql function only returns the first result set, which is appropriate in most cases. If you need to determine all result sets returned by a query, the msql function must be used. This function is invoked in exactly the same way as the sql function, but returns a list with all the result sets and/or row counts of the query.

Example:

`> odbc::msql db "select * from pet; select * from event" [];

This will return a list with two result sets, one for each query.

## 24.6 Low-Level Operations

The sql and msql operations are in fact just ordinary Pure functions which are implemented in terms of the low-level operations sql_exec, sql_fetch, sql_more and sql_close. You can also invoke these functions directly if necessary. The sql_exec function starts executing a query and returns either a row count or the column names of the first result set as a tuple of strings. After that you can use sql_fetch to obtain the results in the set one by one. When all rows have been delivered, sql_fetch fails. The sql_more function can then be used to check for additional result sets. If there are further results, sql_more returns either the next row count, or a tuple of column names, after which you can invoke sql_fetch again to obtain the data rows in the second set, etc. When the last result set has been processed, sql_more fails.

Example:

`> odbc::sql_exec db "select name,species from pet where owner='Harold'" [];
["name","species"]
> odbc::sql_fetch db; // get the 1st row
["Fluffy","cat"]
> odbc::sql_fetch db; // get the 2nd row
["Buffy","dog"]
> odbc::sql_fetch db; // no more results
odbc::sql_fetch #<pointer 0x24753e0>
> odbc::sql_more db; // no more result sets
odbc::sql_more #<pointer 0x24753e0>

Moreover, the sql_close function can be called at any time to terminate an SQL query, after which subsequent calls to sql_fetch and sql_more will fail:

`> odbc::sql_close db; // terminate query ()

This is not strictly necessary (it will be done automatically as soon as the next SQL query is invoked), but it is useful in order to release all resources associated with the query, such as parameter values which have to be cached so that they remain accessible to the SQL server. Since these parameters in some cases may use a lot of memory it is better to call sql_close
as soon as you are finished with a query. This is also done automatically by the `sql` and `msql` functions.

Also note that only a single query can be in progress per database connection at any one time. That is, if you invoke `sql_exec` to initiate a new query, a previous query will be terminated automatically. (However, it is possible to execute multiple queries on the same database simultaneously, if you process them through different connections to that database.)

The low-level operations are useful when you have to deal with large result sets where you want to avoid to build the complete list of results in main memory. Instead, these functions allow you to process the individual elements immediately as they are delivered by the `sql_fetch` function. (An alternative method which combines the space efficiency of immediate processing with the convenience of the list representation is discussed in the following section.) Using the low-level operations you can also build your own specialized query engines; take the definitions of `sql` or `msql` as a start and change them according to your needs.

### 24.7 Lazy Processing

As an experimental feature, the `odbc` module also provides two operations `odbc::lsql` and `odbc::lmsql` which work like `odbc::sql` and `odbc::msql` (see Executing SQL Queries above), but return lazy lists (streams) instead. This offers the convenience of a list-based representation without the overhead of keeping entire result sets in memory, which can be prohibitive when working with large amounts of data.

These functions are invoked just like `odbc::sql` and `odbc::msql`, but they return a lazy list of rows (or a lazy list of lazy lists of rows in the case of `lmsql`). For instance:

```plaintext
> odbc::lsql db "select * from pet" []; 
["name","owner","species","sex","birth","death"]:<thunk 0x7ffbb9aa2eb8>
```

Note that the tail of the result list is “thunked” and will only be produced on demand, as you traverse the list. As a simple example, suppose that we just want to print the `name` field of each data row:

```plaintext
> using system;
> do ($name::~->puts name) $ tail $ odbc::lsql db "select * from pet" [];
Fluffy
Claws
Buffy
Fang
Bowser
Chirpy
Whistler
Slim
()
```

Here only one row is in memory at any time while the `do` function is in progress. This keeps memory requirements much lower than when using the `odbc::sql` function which first loads the entire result set into memory. Another advantage is that only those data rows are fetched from the database which are actually needed in the course of the computation.
This can speed up the processing significantly if only a part of the result set is needed. For instance, in the following example we only look at the first two data rows until the desired row is found, so the remaining rows are never fetched from the database:

```lisp
> head [row | row@{name:_} = tail $ odbc::lsql db "select * from pet" [];
    name == "Claws"];
["Claws","Gwen","cat","m","1994-03-17",odbc::SQLNULL]
```

On the other hand, `lsql/lmsql` will usually be somewhat slower than `sql/msql` if the entire result set is being processed. So you should always consider the time/space tradeoffs when deciding which functions to use in a given situation.

Also note that when using `lsql/lmsql`, the query remains in progress as long as the result list is still being processed. (This is different from `sql/msql` which load the complete result set(s) at once after which the query is terminated immediately.) Since only one query can be executed per database connection, this means that only one lazy result set can be processed per database connection at any time. However, as with the lowlevel operations it is possible to do several lazy queries simultaneously if you assign them to different database connections.

## 24.8 Error Handling

When one of the above operations fails because the SQL server reports an error, an error term of the form `odbc::error msg state` will be returned, which specifies an error message and the corresponding SQL state (i.e., error code). A detailed explanation of the state codes can be found in the ODBC documentation. For instance, a reference to a non-existent table will cause a report like the following:

```lisp
> odbc::sql db "select * from pets" [];
odbc::error "[TCX][MyODBC]Table 'test.pets' doesn't exist" "S1000"
```

You can check for such return values and take some appropriate action. By redefining `odbc::error` accordingly, you can also have it generate exceptions or print an error message. For instance:

```lisp
odbc::error msg state = fprintf stderr "%s (%s)\n" (msg,state) $$ ();
```

**Note:** When redefining `odbc::error` in this manner, you should be aware that the return value of `odbc::error` is what will be returned by the other operations of this module in case of an error condition. These return values are checked by other functions such as `sql`. Thus the return value should still indicate that an error has happened, and not be something that might be interpreted as a legal return value, such as an integer or a nonempty tuple. It is usually safe to have `odbc::error` return an empty tuple or throw an exception, but other types of return values should be avoided.
24.9 Caveats and Bugs

Be warned that multiple result sets are not supported by all databases. I also found that some ODBC drivers do not properly implement this feature, even though the database supports it. So you better stay away from this if you want your application to be portable. You can easily implement batched queries using a sequence of single queries instead.

Note that since the exact numeric SQL data types (NUMERIC, DECIMAL) are mapped to Pure double values (which are double precision floating point numbers), there might be a loss of precision in extreme cases. If this is a problem you should explicitly convert these values to strings in your query, which can be done using the SQL CAST function, as in `select cast(1234.56 as char)`.

24.10 Further Information and Examples

For further details about the operations provided by this module please see the odbc.pure file. A sample script illustrating the usage of the module can be found in the examples directory.
This document describes Sql3, a SQLite module for the Pure programming language.

25.1 Introduction

SQLite is a software library that implements an easy to use, self-contained, serverless, zero-configuration, transactional SQL database engine. SQLite is not intended to be an enterprise database engine like Oracle or PostgreSQL. Instead, SQLite strives to be small, fast, reliable, and above all simple. See Appropriate Uses For SQLite.

Sql3 is a wrapper around SQLite’s C interface that provides Pure programmers access to almost all of SQLite’s features, including many that are not available through Pure’s generic ODBC interface.

25.1.1 Simple Example

Here is a simple example that opens a database file “readme.db” (creating it if it does not exist), adds a table “RM”, populates “RM” and executes a query.

```
pure-sql3$> pure -q
>
> using sql3; using namespace sql3;
>
> let dbp = open "readme.db";
```
The Sql3 functions, open, prep and exec encapsulate the core functionality of SQLite, and in many cases are all you need to use SQLite effectively.

**25.1.2 More Examples**

The examples subdirectory of pure-Sql3 contains several files that further illustrate basic usage as well as some of Sql3’s more sophisticated features. These include readme.pure, a short file that contains the examples included herein. If you are using emacs pure-mode you can load readme.pure into a buffer and execute the examples line by line (pressing C-c C-c) (as well as experiment as you go).

**25.1.3 SQLite Documentation**

SQLite’s home page provides excellent documentation regarding its SQL dialect as well as its C interface. Comments in this document regarding SQLite are not meant to be a substitute for the actual documentation and should not be relied upon, other than as general observations which may or may not be accurate. The best way to use Sql3 is to get familiar with SQLite and its C interface and go directly to the SQLite Site Map for authoritative answers to any specific questions that you might have.

In the rest of this document, it is assumed the reader has some familiarity with SQLite and has read *An Introduction To The SQLite C/C++ Interface*.

**25.1.4 Sqlite3 - The SQLite Command-Line Utility**

The SQLite library includes a really nice command-line utility named sqlite3 (or sqlite3.exe on Windows) that allows the user to manually enter and execute SQL statements against a SQLite database (and much more).

This tool is an invaluable aid when working with SQLite in general and with Sql3 in the Pure interpreter in particular. For example, after entering the Pure statements from the Simple Example above, you could start a new terminal, cd to pure-sql3, type “sqlite3 readme.db” at the prompt, and see the effect the Pure statements had on the database:
For bottom up REPL development, sqlite3 and Pure are an excellent combination.

## 25.2 Copying

Copyright (c) 2010 by Peter Summerland <p.summerland@gmail.com>.
Copyright (c) 2010 by Albert Graef <aggraef@gmail.com>.

All rights reserved.

Sql3 is free software: you can redistribute it and/or modify it under the terms of the New BSD License, often referred to as the 3 clause BSD license. Sql3 is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

Please see the COPYING file for the actual license applicable to Sql3.

## 25.3 Installation

Get the latest source from [https://bitbucket.org/purelang/pure-lang/downloads/pure-sql3-0.5.tar.gz](https://bitbucket.org/purelang/pure-lang/downloads/pure-sql3-0.5.tar.gz).

Unless you already have them on your machine, download SQLite and sqlite3 from the SQLite website and install as indicated. To install Sql3, cd to the pure-sql3 directory, run make, and then run sudo make install (on Linux).

## 25.4 Data Structure

From a client’s perspective, the most important of SQLite’s data structures are the database connection object “sqlite3” and the prepared statement object “sqlite3_stmt”. These are opaque data structures that are made available to users of SQLite’s C interface via pointers, sqlite3* and sqlite3_stmt*. At appropriate times, Sql3 creates “cooked” versions of these pointers that can be used (with care) to call native C functions exposed by SQLite’s C interface.

Sql3 introduces two new data types, “db_ptr” and “stmt_ptr” which refer to the cooked versions of sqlite3* and sqlite3_stmt*, respectively. These two new data types are defined using type, and therefore can be used as type tags in rule patterns or as the first parameter passed
to in the typep function. It follows that all db_ptrs are sqlite3* pointers and all stmt_ptrs are sqlite3_stmt* pointers. Thus, using dbp and sp1 from the introductory example:

```plaintext
> typep db_ptr dbp, pointer_type dbp;
1, "sqlite3*"

> typep stmt_ptr sp1, pointer_type sp1;
1, "sqlite3_stmt*"
```

The converse, of course, is not true, as SQLite knows nothing about Sql3, and db_ptrs and stmt_ptrs carry other information in addition to the underlying pointers provided to them by SQLite.

### 25.5 Core Database Operations

The core database operations are (a) opening and closing database connections and (b) preparing, executing and closing prepared statements.

#### 25.5.1 Database Connections

Generally speaking, the first step in accessing a database is to obtain a db_ptr that references a database connection object. Once the db_ptr is obtained, it can be used to construct prepared statements for updating and querying the underlying database. The last step is usually to close the database connection (although this is will be done automatically by Sql3 when the db_ptr goes out of scope).

**Opening a Database Connection**

In Sql3 `open` constructs a database connection and returns a db_ptr that refers to the connection.

```plaintext
sql3::open (file_path::string [,access_mode::int[,custom_bindings]])
```

opens a SQLite database file whose name is given by the file_path argument and returns a db_ptr for the associated database connection object created by SQLite.

Example:

```plaintext
> let dbp2 = open "abc.db"; dbp2;
#<pointer 0x992dff8>
```

If the filename is “:memory:” a private, temporary in-memory database is created for the connection.

The basic access modes are:

- `SQLITE_OPEN_READONLY` - the database is opened in read-only mode. If the database does not already exist, an error is returned.
- `SQLITE_OPEN_READWRITE` - the database is opened for reading and writing if possible, or reading only if the file is write protected by the operating system. In either case the database must already exist, otherwise an error is returned.
• SQLITE_OPEN_READWRITE | SQLITE_OPEN_CREATE - the database is opened for reading and writing, and is creates it if it does not already exist. This is the default value that is used if the flags argument is omitted.

• SQLITE_OPEN - an alias for SQLITE_OPEN_READWRITE | SQLITE_OPEN_CREATE provided by Sql3.

These flags can be combined with SQLITE_OPEN_NOMUTEX SQLITE_OPEN_FULLMUTEX SQLITE_OPEN_SHAREDCACHE SQLITE_OPEN_PRIVATECACHE to control SQLite’s threading and shared cache features. All of these flags are exported by Sql3.

The optional custom_bindings argument allows the user to set up customized binding and fetching behavior for prepared statements associated with the returned db_ptr. (See Custom Binding Types for Prepared Statements)

Failure to Open a Database Connection

If SQLite cannot open the connection, it still returns a pointer to a database connection object that must be closed. In this case, open automatically closes the connection object and then throws an exception. E.g.,:

```c
> catch error (open("RM_zyx.db",SQLITE_OPEN_READONLY));
error (sql3::db_error 14 "unable to open database file [open RM_zyx.db"])
```

Apparently, SQLite does not verify that a file is a valid SQLite database when it opens a connection. However, if the file is corrupted SQLite will return an error when the connection is used.

Testing a db_ptr

You can test any object to see if it is a db_ptr using (typep db_ptr):

```c
(typep db_ptr x)
returns 1 if x is a db_ptr returned by open, and 0 if it is not.
```

You can also determine if a db_ptr’s data connection is open.

```c
sql3::is_open dbp::db_ptr
returns 1 if the database connection referenced by dbp is open.
```

Closing a Database Connection

When a database connection object is no longer needed, it should be closed so that SQLite can free the associated resources.

```c
sql3::close dbp::db_ptr
if the database connection referenced by the db_ptr dbp is open, close it using sqlite3_close; otherwise do nothing.
```
Before calling `sqlite3_close`, `close` finalizes all prepared statements associated with the connection being closed. Sql3 will detect and throw a `db_error` if an attempt is subsequently made to execute a statement associated with the closed database connection.

```pursuit
> let dbp2_sp = prep dbp2 "ci:" "select * from RM";

> exec dbp2_sp ();
[["Sam",20],["Fred",22]]

> close dbp2;

> catch error (exec dbp2_sp);
error (sql3::db_error 0 "Attempt to exec on a closed db_ptr.")
```

If a `db_ptr` goes out of scope, Sql3 will automatically call `sqlite3_close` to close the referenced database connection, but only if the connection has not already been closed by `close`. Thus, for example, it is not necessary to use a catch statement to ensure that Sqlite3 resources are properly finalized when a `db_ptr` is passed into code that could throw an exception.

When debugging, this activity can be observed by editing `sql3.pure`, changing “const SHOW_OPEN_CLOSE = 0;” to “const SHOW_OPEN_CLOSE = 1;” and running `sudo make install` in the `pure-sql3` directory. This will cause a message to be printed whenever a `db_ptr` or `stmt_ptr` is created or finalized.

N.B. You should never call the native C interface function ‘`sqlite3_close`’ with a `db_ptr`. If the referenced database connection is closed by such a call, a subsequent call to `close` on this `db_ptr` (including the call that will automatically occur when the `db_ptr` goes out of scope) will cause a seg fault.

### 25.5.2 Prepared Statements

The native SQLite C interface provides five core functions needed to execute a SQL statement.

- `sqlite3_prepare_v2`
- `sqlite3_bind`
- `sqlite3_step`
- `sqlite3_column`
- `sqlite3_finalize`

Using the C interface, the basic procedure is to prepare a statement using `sqlite3_prepare_v2`, bind its parameters using `sqlite3_bind`, step it using `sqlite3_step` one or more times until it is done and then finalize it using `sqlite3_finalize`. Each time `sqlite3_step` returns `SQLITE_ROW`, use `sqlite3_column` to fetch the row’s values. Here `sqlite3_bind` and `sqlite3_column` represent families of bind and column functions, rather than actual functions, with one member for each of the basic data types recognized by SQLite. Thus, for example, `sqlite_bind_double` is the function one would use to bind a prepared statement with an argument of type double.
Sql3 encapsulates these procedures in four functions: `prep`, `exec`, `lexec` and `finalize`.

### Constructing Prepared Statements

In Sql3 you can use `prep` to construct a prepared statement and obtain a stmt_ptr that refers to it.

```cpp
sql3::prep dbp::db_ptr binding_string::string sql_statement::string
    constructs a prepared statement object and returns a stmt_ptr that references it. dbp
    must be a db_ptr or the rule will not match. sql_statement is the SQL statement that
    will be executed when the prepared statement is passed to exec.
```

Basically, `prep` just passes `dbp` and `sql_statement` on to `sqlite3_prepare_v2` and returns a sentry guarded version of the `sqlite3_stmt*` it receives back from `sqlite3_prepare_v2`. SQL statements passed to `prep` (and `sqlite3_prepare_v2`) can have argument placeholders, indicated by “?”, “?nnn”, “:AAA”, etc, in which case the argument placeholders must be bound to values using `sqlite3_bind` before the prepared statement is passed to `sqlite3_step`. Hence the `binding_string`, which is used by Sql3 to determine how to bind the prepared statement’s argument placeholders, if any. The binding string also tells Sql3 how to fetch values in the `sqlite3_column` phase of the basic prepare, bind, step, fetch, finalize cycle dictated by the SQLite C interface.

In the following two examples, the “c” and “i” in the binding strings indicate that (a) a string and an int will be used to bind `sp1`, (b) an int will be used to bind `sp2` and (c) `sp2`, when executed, will return a result set in the form of a list of sublists each of which contains a string and an int.

```plaintext
> let sp1 = prep dbp "ci" "insert into RM values (?,?)";
> let sp2 = prep dbp "ci:i" "select * from RM where age > ?";
```

In general, the characters in the type string before the “:”, if any, indicate the types in the result set. Those that occur after the “:”, if any, indicate the types of the arguments used to bind the prepared statement object. If the type string does not contain a “:”, the characters in the type string, if any, are the types of binding arguments.

Sql3 provides the following set of “core” binding types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Pure Argument</th>
<th>SQLite Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>(int, pointer)</td>
<td>blob</td>
</tr>
<tr>
<td>c</td>
<td>string</td>
<td>text (utf8)</td>
</tr>
<tr>
<td>d</td>
<td>double</td>
<td>float</td>
</tr>
<tr>
<td>i</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>k</td>
<td>int or bigint</td>
<td>int64</td>
</tr>
<tr>
<td>l</td>
<td>bigint</td>
<td>blob</td>
</tr>
<tr>
<td>n</td>
<td>Sql3::SQLNULL</td>
<td>NULL</td>
</tr>
<tr>
<td>x</td>
<td>expression</td>
<td>blob</td>
</tr>
<tr>
<td>v</td>
<td>variant</td>
<td>variant</td>
</tr>
</tbody>
</table>

The “b” or blob type is different from the rest in that the Pure argument is specified as a

---

25.5.2 Prepared Statements

---

733
pair. The first element of the pair indicates the length in bytes of the object to be stored and the second element indicates its location in memory. The “c” type stands for string (as in “char*”), “d” stands for double and “i” stands for int. The “k” type stands for “key” and maps Pure ints and bigints (within the range of int64) to int64 values in the database. This type is useful when dealing with SQLite’s “integer primary keys” and “rowids” both of which are int64. The “I” type, in contrast applies to all bigints (and not to ints) and it maps bigints onto blobs, which are generally meaningless in SQL math expressions. The “n” type can only appear on the binding side of a type string. The “v” type stands for any of “b”, “c”, “d”, “i” or “n”, based on the type of the binding argument. A “v” type will be fetched from SQLite according to the native SQLite column type of the corresponding column. The “x” type is used to store and reconstruct Pure expressions as binary objects, using the val and blob functions provided by the Pure prelude.

Users can define custom binding types and pass them as a third parameter to open. The resulting db_ptr can be used with the custom binding types to construct prepared statements using prep.

Testing a stmt_ptr

You can determine if a given expression is a stmt_ptr using typep.

```plaintext
typep stmt_ptr x
    returns 1 if x is a stmt_ptr, otherwise returns 0.
```

Executing Prepared Statements

In Sql3, the bind, step, column, step, column ... cycle is encapsulated in the exec and leexec functions.

```plaintext
sql3::exec sp::stmt_ptr args
    use args to bind the prepared statement referenced by sp, execute it and return the result set as a list. The first parameter, sp must be a valid stmt_ptr or the rule will fail.
```

The second parameter, args, is a tuple or list of arguments whose number and type correspond to the bind parameter types specified in the call to prep that produced the first parameter sp.

Thus, using sp1 and sp2 defined in the introductory example:

```plaintext
> exec sp1 ("Tom",30); //insert Tom

> exec sp2 19;       //select age > 19
[["Sam",20],["Fred",22],["Tom",30]]
```

An error is thrown if the args do not correspond to the specified types.

```plaintext
> catch error (exec sp2 "a");
error (sql3::db.error 0 ""a" does not have type int")
```

If a prepared statement does not have any binding parameters, the call to exec should use () as the binding argument.
> let sp3 = prep dbp "c:" "select name from RM";

> exec sp3 ();
[["Sam"], ["Fred"], ["Tom"]]

Extra care is required when executing prepared statements that take a blob argument because it must be a pair. In order to preserve the tuple as a pair, binding arguments that include a blob should passed to exec as a list. If passed as a member of a larger tuple, it will be treated as two arguments due to the nature of tuples.

> let blb = (100, ptr);

> (a, blb, c);
(a, 100, ptr, c)

> [a, blb, c];
[a, (100, ptr), c]

Thus something like "exec stpx [a, blb, c]" would work fine, while "exec stpx (a, blb, c)" would produce a Sql3 binding exception.

**Executing Lazily**

The exec function returns result sets as eager lists which can sometimes be inefficient or simply not feasible for large result sets. In such cases it is preferable to use leexec instead of exec.

```sql3::leexec stmt::stmt_ptr args
    same as exec except that it returns a lazy list.
```

Example:

> leexec sp2 19;
[["Sam", 20]: #<thunk 0xb6475ab0>]

Note that no changes to sp2 were required. In addition, for most purposes the lazy list returned by leexec can be processed by the same code that processed the eager list returned by exec.

**Executing Directly on a db_ptr**

For statements that have no parameters and which do not return results, exec can be applied to a db_ptr.

```sql3::exec dbp::db_ptr sql_statement::string
    constructs a temporary prepared statement using sql_statement. The SQL statement cannot contain argument placeholders and cannot be a select statement.
```

Example:
> exec dbp "create table if not exists RM (name varchar, age integer)";

### Executing Against a Busy Database

SQLite allows multiple processes to concurrently read a single database, but when any process wants to write, it locks the entire database file for the duration of its update.

When the native SQLite C interface function `sqlite3_step` (used by `exec`) tries to access a file that is locked by another process, it treats the database as “busy” and returns the SQLITE_BUSY error code. If this happens in a call to `exec` or `lexec`, a `db_busy` exception will be thrown.

You can adjust SQLite’s behavior using `sqlite3_busy_handler` or `sqlite3_busy_timeout`.

If the statement is a COMMIT or occurs outside of an explicit transaction, then you can retry the statement. If the statement is not a COMMIT and occurs within a explicit transaction then you should rollback the transaction before continuing.

### Grouping Execution with Transactions

No changes can be made to a SQLite database file except within a transaction. Transactions can be started manually by executing a BEGIN statement (i.e., `exec dbp "BEGIN"`). Manually started transactions persist until the next COMMIT or ROLLBACK statement is executed. Transactions are also ended if an error occurs before the transaction is manually ended using a COMMIT or ROLLBACK statement. This behavior provides the means make a series of changes “atomically.”

By default, SQLite operates in autocommit mode. In autocommit mode, any SQL statement that changes the database (basically, anything other than SELECT) will automatically start a transaction if one is not already in effect. As opposed to manually started transactions, automatically started transactions are committed as soon as the execution of the related statement completes.

The upshot of this, in Sql3 terms, is that unless a transaction is started manually, the database will be updated each time `exec` is called. For a long series of updates or inserts this can be very slow. The way to avoid this problem is to manually begin and end transactions manually.

Sql3 provides the following convenience functions all of which simply call `exec` with the appropriate statement. For example `begin dbp` is exactly the same as `exec dbp "BEGIN"`.

```
sql3::begin dbp::db_ptr
sql3::begin_exclusive dbp::db_ptr
sql3::begin_immediate dbp::db_ptr
sql3::commit dbp::db_ptr
sql3::rollback dbp::db_ptr
sql3::savepoint dbp::db_ptr save_point::string
```
sql3::release dbp::db_ptr save_point::string
sql3::rollback_to dbp::db_ptr save_point::string

Note that transactions created using begin and commit do not nest. For nested transactions, use savepoint and release.

Finalizing Prepared Statements

When a prepared statement is no longer needed it should be finalized so that SQLite can free the associated resources.

sql3::finalize sp::stmt_ptr
finalizes the prepared statement referenced by sp, which must be a stmt_ptr previously returned by prep.

Often there is no need to call finalize for a given stmt_ptr because it will be automatically called when the stmt_ptr goes out of scope.

If the stmt_ptr is associated with a database connection that has been closed (which would have caused an exception to be thrown), an attempt to finalize it, including the automatic finalization can occur when stmt_ptr goes out of scope, will cause an exception to be thrown.

```c++
> catch error (finalize dbp2_sp);
error (sql3::db_error 0 "finalize: STMT attached to a closed db_ptr.")
```

Multiple calls to finalize are fine. In contrast, the corresponding native C interface function, sqlite3_finalize will cause a seg fault if called with a pointer to a finalized prepared statement object. This is the main reason why you should never call sqlite3_finalize with a stmt_ptr. If the prepared statement referenced by the stmt_ptr is finalized by such a call, a subsequent call to finalize with the stmt_ptr (including the call that will automatically occur when the stmt_ptr goes out of scope) will cause a seg fault.

25.5.3 Exceptions

Sql3 throws two types of exceptions, one for outright errors and one for database “busy” conditions.

**constructor sql3::db_error ec msg**

When a Sql3 function detects an error it throws an exception of the form “db_error ec msg” where ec is an error code and msg is the corresponding error message. If ec>0, the error was detected by SQLite itself, and ec and msg are those returned by SQLite. If ec==0, the error was detected by Sql3 and msg is a Sql3 specific description of the error. E.g.,

```c++
> db_error_handler (db_error ec msg) = ()
> when
>   source = if ec > 0 then "SQLite" else "Sql3";
>   printf "%s db_error: ec %d, %s\n" (source,ec,msg);
> end;
> db_error_handler x = throw x;
```
> catch db_error_handler (exec dbp "select * from NO_TABLE");
SQLite db_error: ec 1, no such table: NO_TABLE

constructor sql3::db_busy dbp

Sql3 functions exec and lexec throw exceptions of the form “db_busy dbp”, where dbp is a db_ptr, if they are prevented from executing successfully because the database referenced by dbp is locked (See Executing Against a Busy Database).

SQLite Error Codes

Here is a list, as of January 31, 2011, of SQLite’s error codes.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLITE_ERROR</td>
<td>1 /* SQL error or missing database */</td>
</tr>
<tr>
<td>SQLITE_INTERNAL</td>
<td>2 /* Internal logic error in SQLite */</td>
</tr>
<tr>
<td>SQLITE_PERM</td>
<td>3 /* Access permission denied */</td>
</tr>
<tr>
<td>SQLITE_ABORT</td>
<td>4 /* Callback routine requested an abort */</td>
</tr>
<tr>
<td>SQLITE_BUSY</td>
<td>5 /* The database file is locked */</td>
</tr>
<tr>
<td>SQLITE_LOCKED</td>
<td>6 /* A table in the database is locked */</td>
</tr>
<tr>
<td>SQLITE_NOMEM</td>
<td>7 /* A malloc() failed */</td>
</tr>
<tr>
<td>SQLITE_READONLY</td>
<td>8 /* Attempt to write a readonly database */</td>
</tr>
<tr>
<td>SQLITE_INTERRUPT</td>
<td>9 /* Operation terminated by sqlite3_interrupt()*/</td>
</tr>
<tr>
<td>SQLITE_IOERR</td>
<td>10 /* Some kind of disk I/O error occurred */</td>
</tr>
<tr>
<td>SQLITE_CORRUPT</td>
<td>11 /* The database disk image is malformed */</td>
</tr>
<tr>
<td>SQLITE_NOTFOUND</td>
<td>12 /* NOT USED. Table or record not found */</td>
</tr>
<tr>
<td>SQLITE_FULL</td>
<td>13 /* Insertion failed because database is full */</td>
</tr>
<tr>
<td>SQLITE_CANTOPEN</td>
<td>14 /* Unable to open the database file */</td>
</tr>
<tr>
<td>SQLITE_PROTOCOL</td>
<td>15 /* NOT USED. Database lock protocol error */</td>
</tr>
<tr>
<td>SQLITE_EMPTY</td>
<td>16 /* Database is empty */</td>
</tr>
<tr>
<td>SQLITE_SCHEMA</td>
<td>17 /* The database schema changed */</td>
</tr>
<tr>
<td>SQLITE_TOOBIG</td>
<td>18 /* String or BLOB exceeds size limit */</td>
</tr>
<tr>
<td>SQLITE_CONSTRAINT</td>
<td>19 /* Abort due to constraint violation */</td>
</tr>
<tr>
<td>SQLITE_MISMATCH</td>
<td>20 /* Data type mismatch */</td>
</tr>
<tr>
<td>SQLITE_MISUSE</td>
<td>21 /* Library used incorrectly */</td>
</tr>
<tr>
<td>SQLITE_NOLFS</td>
<td>22 /* Uses OS features not supported on host */</td>
</tr>
<tr>
<td>SQLITE_AUTH</td>
<td>23 /* Authorization denied */</td>
</tr>
<tr>
<td>SQLITE_FORMAT</td>
<td>24 /* Auxiliary database format error */</td>
</tr>
<tr>
<td>SQLITE_RANGE</td>
<td>25 /* 2nd parameter to sqlite3_bind out of range */</td>
</tr>
<tr>
<td>SQLITE_NOTADB</td>
<td>26 /* File opened that is not a database file */</td>
</tr>
</tbody>
</table>

New error codes may be added in future versions of SQLite. Note that the SQLite names of the error codes are not exported by the Sql3 module.

25.6 Advanced Features

Sql3’s advanced features include the ability to implement SQL functions in Pure, convenient access to the SQLite C interface and custom binding types.
25.6.1 Custom SQL Functions

An extremely powerful (albeit complex) feature of the SQLite C interface is the ability to add new SQL scalar or aggregate functions. The new functions can be used in SQL statements the same way as SQLite's prepackaged functions. Sql3 hides the complexity and seamlessly integrates all of this functionality, into Pure via `create_function`. This function is used to register both scalar SQL functions and aggregate SQL functions with SQLite.

Scalar SQL Functions

You can add a custom SQL scalar function to SQLite by passing a single Pure function to `create_function`.

```pure
sql3::create_function dbp::db_ptr name::string nargs::int pure_fun
    registers a new SQL scalar function of `nargs` arguments that can be called, as name, in SQL statements prepared with respect to `dbp`, a db_ptr. When the SQL function is called in a SQL statement, control is passed to `pure_fun`, a function written in Pure. If `nargs` is (-1), the SQL function name is variadic, and the arguments will be passed to `pure_fun` as a single list.

Note that `create_function` can also register aggregate functions (see Aggregate SQL Functions).

Here is an example of a scalar function that takes two parameters. Note that any kind of Pure "function" can be passed here; local functions, global functions, lambdas or partial applications all work.

```pure
> create_function dbp::dbp "p_fn" 2 plus with plus x y = x + y; end;
> let sp4 = prep dbp "cii:" "select p_fn('Hi ',name), age, p_fn(age,10) from RM";
> exec sp4 ();
[ [ "Hi Sam",20,30], [ "Hi Fred",22,32] ]
```

Here is an example of a variadic function:

```pure
> create_function dbp::dbp "p_qm" (-1) quasimodo with
>    quasimodo xs = "quasimodo: "+join ":" [str x | x=xs];
> end;

Here is an example of a variadic function:

```pure
> create_function dbp::dbp "p_count" 0 counter with
>    counter () = put r (get r+1);
> end when r = ref 0 end;

Here is how count and quasimodo might be used:

```pure
> let sp5 = prep dbp "ic:" "select p_count(), p_qm(name,age) from RM";
```
> exec sp5 ();
[[1,"quasimodo: "Sam":20"],[2,"quasimodo: "Fred":22"]]

> exec sp5 ();
[[3,"quasimodo: "Sam":20"],[4,"quasimodo: "Fred":22"]]

Multiple SQL functions can be registered with the same name if they have differing numbers of arguments. Built-in SQL functions may be overloaded or replaced by new application-defined functions.

Generally, a custom function is permitted to call other Sql3 and native SQLite C interface functions. However, such calls must not close the database connection nor finalize or reset the prepared statement in which the function is running.

### Aggregate SQL Functions

You can use `create_function` to register an aggregate SQL function with SQLite by passing a triple consisting of two Pure functions and a start value, in lieu of a single Pure function.

```argout
sql3::create_function dbp::db_ptr name::string nargs::int (step,final,start)
    registers a new SQL aggregate function of nargs arguments that can be called, as name in SQL statements prepared with respect to dbp, a db_ptr. step and final are curried Pure functions and start is the initial value for the aggregation. The step function is called repeatedly to accumulate values from the database, starting from the given start value, and finally the final function is applied to the accumulated result.
```

Note that for a single-argument step function, this works exactly as if the functions were invoked as “final (foldl step start values)”, where values is the list of aggregated values from the database.

```argout
> create_function dbp "p_avg" 1 (step,final,(0,0.0)) with
>     step (n,a) x = n+1, a+x;
>     final (n,a) = a/n;
> end;

> let sp6 = prep dbp "id:" "select count(name), p_avg(age) from RM";

> exec sp6 ();
[[2,21.0]]
```

### 25.6.2 Accessing the Rest of SQLite’s C Interface

The db_ptrs returned by `open` and stmt_ptrs returned by `prep` are sentry guarded versions of the actual pointers to the data base connection objects and prepared statement objects returned by their corresponding native C interface functions sqlite3_open_v2 and sqlite3_prepare_v2. This makes it easy to call almost any external function in SQLite’s C interface directly, passing it the same db_ptr or stmt_ptr that is passed to Sql3’s functions, such as `prep` or `exec.`
For example, you can override SQLite’s default behavior with respect to a busy database as follows:

```c
> extern int sqlite3_busy_timeout(sqlite3*, int);
> sqlite3_busy_timeout dbp 10;
```

This sets a busy handler that will “sleep and retry” multiple times until at least 10 milliseconds of sleeping have accumulated. Calling this routine with an argument less than or equal to zero turns off all busy handlers.

Another example is to query the number of database rows that were changed, inserted or deleted by the most recently completed SQL statement executed on a given database connection:

```c
> extern int sqlite3_changes(sqlite3*);
> exec sp1 ("Harvey",30);
> sqlite3_changes dbp;
1
```

As a final example, in this case using a stmt_ptr, you can determine name assigned to a column in a result using sqlite3_column_name:

```c
> extern char *sqlite3_column_name(sqlite3_stmt*, int);
> exec sp2 29;
[["Harvey",30]]
> sqlite3_column_name sp2 1;
"age"
```

In order to call a native C function you must first make it accessible using an extern statement.

Please note also that directly calling a function provided by the SQLite C interface can be dangerous, as is the case with any call from Pure code to an external C function. Sql3 users should be especially careful in this regard because using a db_ptr or a stmt_ptr in calls to certain native C interface functions, including in particular sqlite3_close and sqlite3_finalize, will corrupt data held by the db_ptr or stmt_ptr, leading to undefined behavior. The reason for this restriction is that Sql3 uses sentries to insure that the resources associated with a db_ptr or a stmt_ptr are automatically finalized by SQLite when they go out of scope. In addition, the sentries carry internal information used by Sql3 for other purposes.

### 25.6.3 Custom Binding Types for Prepared Statements

You can add your own binding types for preparing and executing prepared statements by specifying a third argument to `open`. The third argument must be a list of “hash rocket pairs” in which the left side is a character for the custom binding type and the right side is a list
with three members. The second and third members of the list are functions that map objects from the new type to one of the Sql3 core types and back, respectively. The first member of the list is the character for the Sql3 core types referenced by the mapping functions.

The file sql3_user_bind_types.pure in the examples subdirectory shows how this might be done for a couple of user defined types. The example script deals with dates and certain Pure expressions as bigints and native Pure expressions, while the database stores these as utf-8 text. The following snippets show parts of the script that are relevant to this discussion:

```pure
const custom_binds = [
  "t"=>["c",day_to_str,str_to_day],
  "s"=>["c",str,eval]
];

d1 = str_to_day "2010-03-22";

db = open ("abc.db", SQLITE_OPEN, custom_binds);
stm1 = prep db "cts" "insert into TC values(?,?,?)";
exec stm1 ["Manny", d1, s_expr];
stm3a = sql3::prep db "t:" "select t_date from TC";
stm3b = sql3::prep db "c:" "select t_date from TC";

Executing stm3a and stm3b from the interpreter shows that TC’s date field is stored as a string, but returned to the Pure script as a bigint.

> ql3::exec stm3a ();
[[14691L]]

> ql3::exec stm3b ();
[['"2010-03-22"]]

The character designating the custom type must not be one of the letters used to designate Sql3 core binding types.

25.7 Threading Modes

SQLite supports three different threading modes:

1. Single-thread. In this mode, all mutexes are disabled and SQLite is unsafe to use in more than a single thread at once.

2. Multi-thread. In this mode, SQLite can be safely used by multiple threads provided that no single database connection is used simultaneously in two or more threads.

3. Serialized. In serialized mode, SQLite can be safely used by multiple threads with no restriction.

SQLite can be compiled with or without support for multithreading and the default is to support it.

In many cases, single-thread mode might be appropriate if only because it is measurably faster. This might be the case, for example, if you are using SQLite as the on-disk file format.
for a desktop application.

If your version of SQLite was compiled with support for multithreading, you can switch to single-thread mode at runtime by calling sqlite3_config() with the verb SQLITE_CONFIG_SINGLETHREAD.

If you must use threads, it is anticipated that Sql3 probably will not impose an additional burden. Hopefully, you will be fine if you apply the same precautions to a db_ptr or stmt_ptr that you would apply to the underlying sqlite* and sqlite_stmt*s if you were not using Sql3. It is strongly advised however that you look at the underlying Sql3 code to verify that this will work. Since everything that is imposed between the raw pointers returned by the Sqlite interface and the corresponding db_ptr and stmt_ptrs is written in Pure, it should be relatively easy to determine how Sql3 and your multithreading strategy will interact. See Is SQLite threadsafe? , Opening A New Database Connection and Test To See If The Library Is Threadsafe.
Chapter 26

Pure-XML - XML/XSLT interface

Version 0.7, April 11, 2018
Albert Graef <aggraef@gmail.com>

XML, the Extensible Markup Language, facilitates the exchange of complex structured data between applications and systems. XSLT allows you to transform XML documents to other XML-based formats such as HTML. Together, XML and XSLT let you create dynamic web content with ease. Both XML and XSLT are open standards by the W3C consortium (http://www.w3.org).

Pure’s XML interface is based on the libxml2 and libxslt libraries from the GNOME project. If you have a Linux system then you most likely have these libraries, otherwise you can get them from http://xmlsoft.org. For Windows users, the required dlls are available from the GnuWin32 project (http://gnuwin32.sourceforge.net) and are already included in the Pure MSI package.

26.1 Copying

Copyright (c) 2009 by Albert Graef <aggraef@gmail.com>.

pure-xml is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-xml is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.
26.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-xml-0.7.tar.gz.

Run `make` and then `sudo make install` to compile and install this module. This requires libxml2, libxslt and Pure.

26.3 Usage

Use the following declaration to make the operations of this module available in your programs:

```pure
using xml;
```

The module defines two namespaces `xml` and `xslt` for the XML and the XSLT operations, respectively. For convenience, you can open these in your program as follows:

```pure
using namespace xml, xslt;
```

A number of complete examples illustrating the use of this module can be found in the examples directory in the source distribution.

26.4 Data Structure

This module represents XML documents using pointers to the `xmlDoc` and `xmlNode` structures provided by the libxml2 library. Similarly, stylesheets are simply pointers to the `xmlStylesheet` structure from libxslt (cf. Transformations). This makes it possible to use these objects directly with the operations of the libxml2 and libxslt libraries (via Pure’s C interface) if necessary. Note, however, that these are all “cooked” pointers which take care of freeing themselves automatically when they are no longer needed, therefore you shouldn’t free them manually.

You can also check for these types of pointers using the following predicates:

```pure
xml::docp x
checks whether x is an XML document pointer.

xml::nodep x
checks whether x is a pointer to a node in an XML document.

xslt::stylesheetp x
checks whether x is an XSLT stylesheet pointer.
```

26.4.1 The Document Tree

An XML document is a rooted tree which can be created, traversed and manipulated using the operations of this module. There are different types of nodes in the tree, each carrying their own type of data. In Pure land, the node data is described using the following “node info” constructors.
**constructor** xml::element tag ns attrs

An XML element with given (possibly qualified) name tag, a (possibly empty) list of namespace declarations ns and a (possibly empty) list of attributes attrs. Namespace declarations normally take the form of a pair of strings (prefix,href), where prefix is the prefix associated with the namespace and href the corresponding URI (the name of the namespace), but they can also be just a string href if the namespace prefix is missing. Attributes are encoded as key=>value pairs, where key is the attribute name and value the associated value; both key and value are strings.

**constructor** xml::element_text tag ns attrs content

A convenience function which denotes a combination of an element node with a text child. This is only used when creating a new node, and indicates that a text node child is to be added to the node automatically.

**constructor** xml::attr key val

An attribute node. These only occur as results of the select and attrs functions, and cannot be inserted directly into a document.

**constructor** xml::text content

A text node with the given content (a string).

**constructor** xml::cdata content

Like xml::text, but contains unparsed character data.

**constructor** xml::comment content

A comment.

**constructor** xml::entity_ref name

An entity reference (&name;).

**constructor** xml::pi name content

Processing instructions. name is the application name, content the text of the processing instructions.

### 26.4.2 Document Types

Besides the node types described above, there are some additional node types used in the document type definition (DTD), which can be extracted from a document using the int_subset and ext_subset functions. These are for inspection purposes only; it is not possible to change the DTD of a document in-place. (However, you can create a new document and attach a DTD to it, using the new_doc function.)

**constructor** xml::doctype name extid

DTDs are represented using this special type of node, where name is the name of the root element, and extid is a pair consisting of the external identifier and the URI of the DTD (or just the URI if there is no external identifier). The xml::doctype node has as its children zero or more of the following kinds of DTD declaration nodes (these are just straightforward abstract syntax for the !ELEMENT, !ATTLIST and !ENTITY declarations inside a DTD declaration; see the XML specification for details).

*Element declarations:* Here, name is the element tag and content the definition of the element...
structure, see element content below. XML supports various kinds of element types, please refer to document type definition in the XML specification for details.

**constructor** xml::undefined_element name
An undefined element. This is in libxml2, but not in the XML specification, you shouldn’t see this in normal operation.

**constructor** xml::empty_element name
An element without any content.

**constructor** xml::any_element name
An element with unrestricted content.

**constructor** xml::mixed_element name content
A “mixed” element which can contain character data, optionally interspersed with child elements, as given in the content specification.

**constructor** xml::std_element name content
A standard element consisting only of child elements, as given in the content specification.

**Attribute declarations:** These are used to declare the attributes of an element. elem.name is the name of an element which describes the attribute type, name is the name of the attribute itself, and default specifies the default value of the attribute, see attribute defaults below. XML supports a bunch of different attribute types, please refer to document type definition in the XML specification for details.

**constructor** xml::cdata_attr elem.name name default
**constructor** xml::id_attr elem.name name default
**constructor** xml::idref_attr elem.name name default
**constructor** xml::idrefs_attr elem.name name default
**constructor** xml::entity_attr elem.name name default
**constructor** xml::entities_attr elem.name name default
**constructor** xml::nmtoken_attr elem.name name default
**constructor** xml::nmtokens_attr elem.name name default
**constructor** xml::enum_attr elem.name name vals default
**constructor** xml::notation_attr elem.name name vals default

**Entity declarations:** These are used for internal and external entity declarations. name is the entity name and content its definition. External entities also have an extid (external identifier/URI pair) identifying the entity.

**constructor** xml::int_entity name content
**constructor** xml::int_param_entity name content
**constructor** xml::ext_entity name extid content
The element content type (content argument of the element declaration nodes) is a kind of regular expression formed with tags (specified as strings) and the following constructors:

**Constructor** xml::ext_param_entity name extid content

The following constructors are used:

**Constructor** xml::pcdata
text data (#PCDATA)

**Constructor** xml::sequence xs
concatenation \(x, y, z\)

**Constructor** xml::union xs
alternatives \(x | y | z\)

**Constructor** xml::opt x
optional element \(x?\)

**Constructor** xml::mult x
repeated element \(x^*\)

**Constructor** xml::plus x
non-optional repeated element \(x^+\)

Attribute defaults (the default argument of attribute declaration nodes) are represented using the following constructor symbols:

**Constructor** xml::required
a required attribute, i.e., the user must specify this

**Constructor** xml::implied
an implied attribute, i.e., the user does not have to specify this

**Constructor** xml::default val
an attribute with the given default value val

**Constructor** xml::fixed val
an attribute with the given fixed value val

### 26.5 Operations

This module provides all operations necessary to create, inspect and manipulate XML documents residing either in memory or on disk. Operations for formatting XML documents using XSLT stylesheets are also available.

#### 26.5.1 Document Operations

The following functions allow you to create new XML documents, load them from or save them to a file or a string, and provide general information about a document.

**xml::new_doc** version dtd info
This function creates an XML document. It returns a pointer to the new document. version is a string denoting the XML version (or "" to indicate the default). info is the node info of the root node (which should denote an element node). dtd denotes the...
document type which can be () to denote an empty DTD, a string (the URI/filename of the DTD), or a pair (pubid, sysid) where pubid denotes the public identifier of the DTD and sysid its system identifier (URI).

Note that only simple kinds of documents with an internal DTD can be created this way. Use the `load_file` or `load_string` function below to create a skeleton document if a more elaborate prolog is required.

```xml
xml::load_file name flags
xml::load_string s flags
```

Load an XML document from a file name or a string s. `flags` denotes the parser flags, a bitwise disjunction of any of the following constants, or 0 for the default:

- `xml::DTDLOAD`: load DTD
- `xml::DTDVALID`: validate
- `xml::PEDANTIC`: pedantic parse
- `xml::SUBENT`: substitute entities
- `xml::NOBLANKS`: suppress blank nodes

The return value is the document pointer. These operations may also fail if there is a fatal error parsing the document.

```xml
xml::save_file name doc encoding compression
xml::save_string doc
```

Save an XML document doc to a file or a string. When saving to a file, `encoding` denotes the desired encoding (or "" for the default), `compression` the desired level of zlib compression (0 means none, 9 is maximum, -1 indicates the default). Note that with `xml::save_string`, the result is always encoded as UTF-8.

```xml
xml::doc_info doc
```

Retrieve general information about a document. Returns a tuple `(version, encoding, url, compression, standalone)`, where `version` is the XML version of the document, `encoding` the external encoding (if any), `url` the name/location of the document (if any), `compression` the level of zlib compression, and `standalone` is a flag indicating whether the document contains any external markup declarations "which affect the information passed from the XML processor to the application", see the section on the standalone document declaration in the XML spec for details. (Apparently, in libxml2 `standalone` is either a truth value or one of the special values -1, indicating that there's no XML declaration in the prolog, or -2, indicating that there's an XML declaration but no standalone attribute.)

```xml
xml::int_subset doc
xml::ext_subset doc
```

Retrieve the internal and external DTD subset of a document. Returns a doctype node (fails if there's no corresponding DTD).

Example
Read the sample.xml document distributed with the sources (ignoring blank nodes) and retrieve the document info:

```xml
> using xml;
> let sample = xml::load_file "sample.xml" xml::NOBLANKS;
> xml::doc_info sample;
"1.0" ,"" ,"sample.xml" ,0, -2
```

### 26.5.2 Traversing Documents

These operations are used to traverse the document tree, i.e., the nodes of the document. They take either a document pointer `doc` or a node pointer `node` as argument, and yield a corresponding node pointer (or a document pointer, in the case of `xml::doc`). The node pointers can then be used with the Node Information and Node Manipulation operations described below.

```xml
xml::root doc
    the root node of `doc`

xml::doc node
    the document node belongs to

xml::parent node
    the parent of `node`

xml::first node
xml::last node
    first and last child node

xml::next node
xml::prev node
    next and previous sibling

xml::first_attr node
xml::last_attr node
    first and last attribute node
```

All these operations fail if the corresponding target node does not exist, or if the type of the given node is not supported by this implementation.

There are also two convenience functions to retrieve the children and attribute nodes of a node:

```xml
xml::children node
    returns the list of all child nodes of `node`

xml::attrs node
    returns the list of all attribute nodes of `node`
```

Moreover, given a node pointer `node`, `node!i` can be used to retrieve the `i`th child of `node`.

**Example**

Peek at the root node of the sample document and its children:
> let r = xml::root sample; r;
#<pointer 0xe15e10>
> xml::node_info r;
xml::element "story" [] []
> #xml::children r;
5
> xml::node_info (r!0);
xml::cdata "<greeting>Hello, world!</greeting>"

### 26.5.3 Node Information

These operations retrieve information about the nodes of an XML document.

```ruth
xml::select doc xpath
xml::select doc (xpath,ns)
```

Retrieve nodes using an XPath specification. Given an XPath (a string) `xpath`, this operation returns the list of all matching nodes in the given document `doc`. You can also specify a node as the first argument, in which case the document of the given node is searched and paths are interpreted relative to the given node (rather than the root node of the document).

Moreover, instead of just an XPath you can also specify a pair `(xpath,ns)` consisting of an XPath `xpath` and a list `ns` of `prefix=>uri` string pairs which describe the namespaces to be recognized in the XPath expression. This is necessary to select nodes by qualified tag or attribute names. Note that only the namespace URIs must match up with those used in the queried document; the corresponding namespace prefixes can be chosen freely, so you can use whatever prefixes are convenient to formulate the XPath query. However, for each namespace prefix used in the XPath expression (not the document!), there must be a corresponding binding in the `ns` list. Otherwise the underlying libxml2 function will complain about an undefined namespace prefix and `xml::select` will fail.

```ruth
xml::node_info node
xml::is_blank_node
xml::node_base node
xml::node_path node
xml::node_content node
```

Retrieve the node data from `node`. Returns a `node_info` value, as described in Data Structure above. Fails if the node does not belong to one of the supported node types.

Checks whether a node is a blank node (empty or whitespace only) and thus possibly ignorable.

Returns the base URI of the given node.

Returns the path of a node in the document, in the format accepted by `select`.

Returns the text carried by the node, if any (after entity substitution).

In addition, you can retrieve and change attributes of element nodes with the following operations:
xml::node_attr node name
Retrieves the value of the attribute with the given name (after entity substitution).

xml::set_node_attr node name value
xml::unset_node_attr node name
Sets or unsets an attribute value.

Examples
Set and unset a node attribute:

```
> xml::set_node_attr r "foo" "4711";
()>
> xml::node_info r;
xml::element "story" [] ["foo"=>"4711"]>
> xml::node_attr r "foo";
"4711"
> xml::unset_node_attr r "foo";
()
> xml::node_info r;
xml::element "story" [] []
```

The select function is very powerful, and probably the single most important operation of this module if you want to extract information from an existing XML document without traversing the entire structure. Here is a very simple example of its use:

```
> [xml::node_content n, xml::node_path n | n = xml::select sample "//author";
[(["John Fleck","/story/storyinfo/author"])]

Note that if the XPath expression contains qualified names, the corresponding namespace prefixes and their URIs must be given in the second argument along with the XPath, as follows:

```xml::select doc "/foo:bar", ["foo"=>"http://www.foo.org"]
```

26.5.4 Node Manipulation

These operations enable you to manipulate the document structure by adding a new node to the document tree (specified through its node info), and by removing (unlinking) existing nodes from the tree.

xml::replace node info
Add the new node specified by info in place of the given node node.

xml::add_first node info
xml::add_last node info
Add the new node as the first or last child of node, respectively.

xml::add_next node info
xml::add_prev node info
Add the new node as the next or previous sibling of node, respectively.

The operations above all return a pointer to the new XML node object.
xml::unlink node

Deletes an existing node from the document tree. Returns ()

Examples

Replace the first child of the root node in the sample document:

```xml
> xml::node_info (r!0);
xml::cdata "<greeting>Hello, world!</greeting>"
> xml::replace (r!0) (xml::text "bla bla")
#<pointer 0xd40d80>
> xml::node_info (r!0);
xml::text "bla bla"
```

Delete that node:

```xml
> xml::unlink (r!0);
()
> xml::node_info (r!0);
xml::comment "This is a sample document for testing the xml interface."
```

26.5.5 Transformations

The following operations provide basic XSLT support. As already mentioned, stylesheets are represented as pointers to the xsltStylesheet structure provided by libxslt. Note that, in difference to XML document pointers, this is an opaque type, i.e., there is no direct means to inspect and manipulate parsed stylesheets in memory using the operations of this module. However, a stylesheet is just a special kind of XML document and thus can be manipulated after reading the stylesheet as an ordinary XML document. The `load_stylesheet` function then allows you to convert the document pointer to an XSLT Stylesheet object.

Applying a stylesheet to an XML document generally involves the following steps:

1. Load and parse the stylesheet using `load_stylesheet`. The parameter to `load_stylesheet` can be either the name of a stylesheet file or a corresponding document pointer. The function returns a pointer to the stylesheet object which is used in the subsequent processing.

2. Invoke `apply_stylesheet` on the stylesheet and the target document. This returns a new document containing the transformed XML document.

3. Run `save_result_file` or `save_result_string` on the result and the stylesheet to save the transformed document in a file or a string.

Here is a brief summary of the XSLT operations. Please check the XSLT documentation for details of the transformation process.

```xml
xslt::load_stylesheet x
    Load a stylesheet. x can be either an XML document pointer, or a string denoting the desired .xsl file.

xslt::apply_stylesheet style doc params
    Apply the stylesheet style to the given document doc with the given parameters
```
params. The third argument is a (possibly empty) list of key=>value string pairs which allows you to pass additional parameters to the stylesheet.

```plaintext
xslt::save_result_file name doc style compression
xslt::save_result_string doc style
```

Save the transformation result doc obtained with the stylesheet style to a file or a string. This works pretty much like save_file or save_string, but also keeps track of some output-related information contained in the stylesheet.

**Example**

Load the recipes.xml document and the recipes.xsl stylesheet distributed with the sources:

```plaintext
> let recipes = xml::load_file "recipes.xml" xml::DTDVALID;
> let style = xslt::load_stylesheet "recipes.xsl";
```

Apply the stylesheet to the document and save the result in a html file:

```plaintext
> let res = xslt::apply_stylesheet style recipes [];
> xslt::save_result_file "recipes.html" res style 0;
()```

That’s all. You can now have a look at recipes.html in your favourite web browser.
Chapter 27

pure-g2

Version 0.3, April 11, 2018

Albert Graef <aggraef@gmail.com>

This is a straight wrapper of the g2 graphics library, see http://g2gl.sf.net/.

License: BSD-style, see the COPYING file for details.

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-g2-0.3.tar.gz.

G2 is a simple, no-frills 2D graphics library, distributed under the LGPL. It’s easy to use, portable and supports PostScript, X11, PNG and Win32. Just the kind of thing that you need if you want to quickly knock out some basic graphics, and whipping out the almighty OpenGL or GTK/Cairo seems overkill.

To use this module, you need to have libg2 installed as a shared library (libg2.so, .dll etc.) in a place where the Pure interpreter can find it. The g2 source does not include rules to properly build and install a shared library on modern Linux systems, so we’ve included a little patch named g2-0.72-sharedlib.patch in the pure-g2 package which helps with this. (You still have to run ldconfig on Linux after installing g2. Also note that this patch has only been tested on Linux, for other systems you’ll probably have to edit the g2 Makefile yourself.)

Documentation still needs to be written, so for the time being please see g2.pure and have a look at the examples provided in the distribution.

Run make install to copy g2.pure to the Pure library directory. This tries to guess the prefix under which Pure is installed; if this doesn’t work, you’ll have to set the prefix variable in the Makefile accordingly.

The Makefile also provides the following targets:

- make examples compiles the examples to native executables.
- make clean deletes the native executables for the examples, as well as some graphics files which are produced by running g2_test.pure.
• `make generate` regenerates the `g2.pure` module. This requires that you have `pure-gen` installed, as well as the `g2` header files (you can point `pure-gen` to the prefix under which `g2` is installed with the `g2prefix` variable in the `Makefile`). This step shouldn’t normally be necessary, unless you find that the provided wrapper doesn’t work with your `g2` version. The `g2.pure` in this release has been generated from `g2 0.72`. 
Chapter 28

Pure OpenGL Bindings

Version 0.9, April 11, 2018

Scott Dillard
Albert Graef <aggraef@gmail.com>

These are fairly complete Pure bindings for the OpenGL graphics library, which allow you to do 2D and 3D graphics programming with Pure. The bindings should work out of the box on most contemporary systems which have OpenGL drivers installed, thanks to Scott’s on-demand loading code for the GL functions, which accounts for the fact that different GL implementations will export different functions. (Mostly to account for Microsoft’s Museum of Ancient OpenGL History, otherwise known as opengl32.dll.)

Information about OpenGL can be found at: http://www.opengl.org/

As of pure-gl 0.5, the bindings are now generated using pure-gen instead of Scott’s original OpenGL-specific generator. The stuff needed to do this is included (except pure-gen, which is a separate package available from the Pure website), so that you can regenerate the bindings if necessary.

28.1 Copying

Copyright (c) 2009, Scott E Dillard
Copyright (c) 2009, Albert Graef
Copyright (c) 2002-2005, Sven Panne

pure-gl is distributed under a 3-clause BSD-style license, please see the accompanying COPYING file for details.
28.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-gl-0.9.tar.gz.

Normally you just run make && sudo make install, as with the other Pure modules. (See The Makefile for further options.) This doesn’t regenerate the bindings and so can be done on any system which has Pure, OpenGL and a C compiler installed.

If you miss some vendor-specific OpenGL functionality which is in your system’s header files but not in the distributed bindings, with some effort you can fix that yourself by regenerating the bindings, see below.

28.3 Using the GL Bindings

The bindings mainly consist of 3 Pure files: GL.pure, GLU.pure and GLUT.pure.

In your Pure program, write something like:

```pure
using GL, GLU, GLUT;
```

GL.pure covers OpenGL up through version 2.1. To get access to extensions, you include GL_XXX.pure where XXX is the extensions suffix. Currently, there are GL_ARB.pure, GL_EXT.pure, GL_NV.pure and GL_ATI.pure, which should cover about 99% of the useful extensions out there. If you need more than that, it is straightforward to tweak the Makefile to scrape some of the more esoteric extensions from your headers. All OpenGL functions are loaded on first use. If your OpenGL implementation does not define a given function, a gl_unsupported exception is thrown with the name of the function as its only argument.

The functions are in namespaces GL, GLU and GLUT respectively. Functions are in curried form, i.e.:

```pure
GL::Vertex3d 1.0 2.0 3.0;
```

GL enumerants are in uppercase, as in C:

```pure
GL::Begin GL::LINE_STRIP;
```

Currently, if the GLU or GLUT bindings reference a function that your DLL does not contain, it echoes this to stdout. I’m working on a way to supress this.

Some examples can be found in the examples subdirectory. This also includes a wrapper of Rasterman’s imlib2 library (also generated with pure-gen), and an example which uses this to render an image as a texture.

The examples/flexi-line directory contains Eduardo Cavazos’ port of the flexi-line demo. Run pure flexi-line-auto.pure, sit back and enjoy. There’s also an interactive version of the demo available in flexi-line.pure.
28.4 Regenerating the Bindings

You need to have pure-gen installed to do this.

Also make sure that you have the OpenGL headers installed. By default, the Makefile assumes that they are in the GL subdirectory of /usr/include, you can set the glpath variable in the Makefile accordingly to change this. (Set glpath to the path under which the GL subdirectory resides, not to the GL subdirectory itself. See below for an example.) Note that on Linux systems, /usr/include/GL usually contains the MESA headers. If available, you may want to use your GPU vendor’s headers instead, to get all the extensions available on your system.

Alternatively, you can also just put the headers (gl.h, glext.h, glu.h, glut.h, and any other OpenGL headers that get #included in those) into the GL subdirectory of the pure-gl sources, by copying them over or creating symbolic links to them. This is particularly useful for maintainers, who may want to use a “staged” header set which is different from the installed OpenGL headers. The “.” directory will always be searched first, so you can also just put the vendor-specific headers there. For instance, if you’re like Scott and you use Ubuntu with an Nvidia GPU, then you can do this:

    cd pure-gl/GL
    ln -s /usr/share/doc/nvidia-glx-new-dev/include/GL/gl.h
    ln -s /usr/share/doc/nvidia-glx-new-dev/include/GL/glext.h

Finally, the Makefile also assumes that you have freeglut (an improved GLUT replacement) installed and want all the extensions offered by freeglut. To use the vanilla GLUT without the extensions instead, you only have to change the value of the source variable in the Makefile from GL/all_gl_freeglut.h to GL/all_gl.h. If you use openglut instead of freeglut you will have to change the GL/all_gl_freeglut.h file accordingly.

Once you have set up things to your liking, you can regenerate the bindings by running make as follows:

    make generate

If you need a custom path to the OpenGL headers as described above (say, /usr/local/include) then do this instead:

    make generate glpath=/usr/local/include

If you’re lucky, this will regenerate all the GL*.pure and GL*.c files, and recompile the shared module from the GL*.c files after that. This shared module, instead of the OpenGL libraries themselves, is what gets loaded by the Pure modules.

If you’re not so lucky, save a complete build log with all the error messages and ask on the pure-lang mailing list for help.

See the “Generator stuff” section in the Makefile for further options. Adding a rule for other extensions should be easy, just have a look at an existing one (e.g., GL_EXT.c) and modify it accordingly.
Pure GTK+ Bindings

Version 0.13, April 11, 2018

Albert Graef <aggraef@gmail.com>

pure-gtk is a collection of bindings to use the GTK+ GUI toolkit version 2.x with Pure, see http://www.gtk.org. The bindings include the gtk (+gdk), glib, atk, cairo and pango libraries, each in their own Pure module.

At present these are just straight 1-1 wrappers of the C libraries, created with pure-gen. So they still lack some convenience, but they are perfectly usable already, and a higher-level API for accessing all the functionality will hopefully become available in time. In fact you can help make that happen. :) So please let me know if you’d like to give a helping hand in improving pure-gtk.

29.1 Copying

Copyright (c) 2008-2011 by Albert Graef.

pure-gtk is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-gtk is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

29.2 Installation

You can get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-gtk-0.13.tar.gz.
For Windows users, a ready-made package in msi format is available from https://bitbucket.org/purelang/pure-lang/downloads/pure-gtk-0.13.msi.

To install from source, do the usual make && sudo make install (see the Makefile for further options). This needs Pure and the GTK header files and libraries. You’ll also need pure-ffi for running the examples.

NOTE: The source release was prepared with GTK+ 2.24.4 on Ubuntu 11.04. If you’re seeing a lot of warnings and/or errors when compiling or loading the modules, your GTK headers are probably much different from these. In that case you should run make generate to regenerate the bindings; for this you also need to have pure-gen installed. (If you already have pure-gen then it’s a good idea to do this anyway.)

29.3 Usage

See examples/hello.pure for a basic example. The files uiexample.pure and uiexample.glade show how to run a GUI created with the Glade-3 interface builder. This needs a recent version of the GtkBuilder API to work. (If you’re still running Glade-2 and an older GTK+ version, you might want to use the older libglade interface instead. Support for that is in the Makefile, but it’s not enabled by default.) NOTE: The examples start up much faster when they are compiled to native executables. To do this, just run make examples after make. (Be patient, this takes a while.)

pure-gtk can be discussed on the Pure mailing list at: http://groups.google.com/group/pure-lang
30.1 Introduction

This module provides a basic interface between Pure and Tcl/Tk. The operations of this module allow you to execute arbitrary commands in the Tcl interpreter, set and retrieve variable values in the interpreter, and invoke Pure callbacks from Tcl/Tk.

A recent version of Tcl/Tk is required (8.0 or later should do). You can get this from http://www.tcl.tk. Both releases in source form and binary releases for Windows and various Unix systems are provided there.

Some information on how to use this module can be found below. But you’ll find that pure-tk is very easy to use, so you might just want to look at the programs in the examples folder to pick it up at a glance. A very basic example can be found in tk_hello.pure; a slightly more advanced example of a tiny but complete Tk application is in tk_examp.pure.

pure-tk also offers special support for Peter G. Baum’s Gnocl extension which turns Tcl into a frontend for GTK+ and Gnome. If you have Gnocl installed then you can easily create GTK+/Gnome applications, either from Tcl sources or from Glade UI files, using the provided gnocl.pure module. See the included uiexample.pure and the accompanying Glade UI file for a simple example. Also, some basic information on using Gnocl with pure-tk can be found in the Tips and Tricks section below.

One nice thing about Tcl/Tk is that it provides a bridge to a lot of other useful libraries. A prominent example is VTK, a powerful open-source 3D visualization toolkit which comes with full Tcl/Tk bindings. The examples directory contains a simple example (earth.pure and earth.tcl) which shows how you can employ these bindings to write cool animated 3D applications using either Tk or Gnocl as the GUI toolkit.
30.2 Copying

Copyright (c) 2010 by Albert Gräf, all rights reserved. pure-tk is distributed under a BSD-style license, see the COPYING file for details.

30.3 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-tk-0.5.tar.gz.

As with the other addon modules for Pure, running make && sudo make install should usually do the trick. This requires that you have Pure and Tcl/Tk installed. make tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, make install prefix=/usr sets the installation prefix. Please see the Makefile for details.

**Note:** When starting a new interpreter, the Tcl/Tk initialization code looks for some initialization files which it executes before anything else happens. Usually these files will be found without any further ado, but if that does not happen automatically, you must set the TCL_LIBRARY and TK_LIBRARY environment variables to point to the Tcl and Tk library directories on your system.

All programs in the examples subdirectory have been set up so that they can be compiled to native executables, and a Makefile is provided in that directory to handle this. So after installing pure-tk you just need to type `make` there to compile the examples. (This step isn’t necessary, though, you can also just run the examples with the Pure interpreter as usual.)

30.4 Basic Usage

**tk cmd**

execute a Tcl command

You can submit a command to the Tcl interpreter with `tk cmd` where `cmd` is a string containing the command to be executed. If the Tcl command returns a value (i.e., a nonempty string) then `tk` returns that string, otherwise it returns `()``.

`tk` also starts a new instance of the Tcl interpreter if it is not already running. To stop the Tcl interpreter, you can use the `tk_quit` function.

**tk_quit**

stop the Tcl interpreter

Note that, as far as pure-tk is concerned, there’s only one Tcl interpreter per process, but of course you can create secondary interpreter instances in the Tcl interpreter using the appropriate Tcl commands.

Simple dialogs can be created directly using Tk’s `tk_messageBox` and `tk_dialog` functions. For instance:
tk "tk.dialog .warning "Warning" "Are you sure?" warning 0 Yes No Cancel";

Other kinds of common dialogs are available; see the Tcl/Tk manual for information.

For more elaborate applications you probably have to explicitly create some widgets, add the appropriate callbacks and provide a main loop which takes care of processing events in the Tcl/Tk GUI. We discuss this in the following.

### 30.5 Callbacks

pure-tk installs a special Tcl command named `pure` in the interpreter which can be used to implement callbacks in Pure. This command is invoked from Tcl as follows:

```
pure function args ...
```

It calls the Pure function named by the first argument, passing any remaining (string) arguments to the callback. If the Pure callback returns a (nonempty) string, that value becomes the return value of the `pure` command, otherwise the result returned to the Tcl interpreter is empty.

Pure callbacks are installed on Tk widgets just like any other, just using the `pure` command as the actual callback command. For instance, you can define a callback which gets invoked when a button is pushed as follows:

```
using tk, system;
tk "button .b -text {Hello, world!} -command {pure hello}; pack .b";
hello = puts "Hello, world!";
```

### 30.6 The Main Loop

```
tk_main
    call the Tk main loop
```

The easiest way to provide a main loop for your application is to just call `tk_main` which keeps processing events in the Tcl interpreter until the interpreter is exited. You can terminate the interpreter in a Pure callback by calling `tk.quit`. Thus a minimalistic Tcl/Tk application coded in Pure may look as follows:

```
using tk;
tk "button .b -text {Hello, world!} -command {pure tk.quit}; pack .b";
tk_main;
```

The main loop terminates as soon as the Tcl interpreter is exited, which can happen, e.g., in response to a callback which invokes the `tk.quit` function (as shown above) or Tcl code which destroys the main window (`destroy .`). The user can also close the main window from the window manager in order to exit the main loop.
30.7 Accessing Tcl Variables

\texttt{tk_set} var val
\texttt{tk_unset} var
\texttt{tk_get} var

set and get Tcl variables

pure-tk allows your script to set and retrieve variable values in the Tcl interpreter with the \texttt{tk_set}, \texttt{tk_unset} and \texttt{tk_get} functions. This is useful, e.g., to change the variables associated with entry and button widgets, and to retrieve the current values from the application. For instance:

\begin{verbatim}
> tk_set "entry_val" "some string";
"some string"
> tk_get "entry_val";
"some string"
> tk_unset "entry_val";
()
> tk_get "entry_val";
"some string"
> tk_unset "entry_val";
()
> tk_get "entry_val";
"some string"
\end{verbatim}

Note that \texttt{tk_set} returns the assigned value, so it is possible to chain such calls if several variables have to be set to the same value:

\begin{verbatim}
> tk_set "foo" $ tk_set "bar" "yes";
"yes"
> map tk_get ["foo","bar);
["yes","yes"
\end{verbatim}

30.8 Conversions Between Pure and Tcl Values

As far as pure-tk is concerned, all Tcl values are strings (in fact, that’s just what they are at the Tcl language level, although the Tcl interpreter uses more elaborate representations of objects such as lists internally). There are no automatic conversions of any kind. Thus, the arguments passed to a Pure callback and the result returned by \texttt{tk} are simply strings in Pure land. The same holds for the \texttt{tk_set} and \texttt{tk_get} functions.

However, there are a few helper functions which can be used to convert between Tcl and Pure data. First, the following operations convert Pure lists to corresponding Tcl lists and vice versa:

\texttt{tk_join} xs
\texttt{tk_split} s

convert between Pure and Tcl lists

\begin{verbatim}
> tk_join ["\theta","1.0","Hello, world!"];
"\theta 1.0 (Hello, world!)"
> tk_split ans;
["\theta","1.0","Hello, world!"]
\end{verbatim}
The `tk_str` and `tk_val` operations work in a similar fashion, but they also do automatic conversions for numeric values (ints, bigints and doubles):

```pure
> tk_str [0,1.0,"Hello, world!"];  
"0 1.0 {Hello, world!}"
> tk_val ans;
[0,1.0,"Hello, world!"]
```

In addition, these operations also convert single atomic values:

```pure
> tk_str 1.0;
"1.0"
> tk_val ans;
1.0
```

### 30.9 Tips and Tricks

Here are a few other things that are worth keeping in mind when working with pure-tk.

- Errors in Tcl/Tk commands can be handled by giving an appropriate definition of the `tk_error` function, which is invoked with an error message as its single argument. For instance, the following implementation of `tk_error` throws an exception:

  ```pure
  tk_error msg = throw msg;
  ```

  If no definition for this function is provided, then errors cause a literal `tk_error msg` expression to be returned as the result of the `tk` function. You can then check for such results and take an appropriate action.

- The Tcl interpreter, when started, displays a default main window, which is required by most Tk applications. If this is not desired (e.g., if only the basic Tcl commands are needed), you can hide this window using a `tk "wm withdraw ."` command. To redisplay the window when it is needed, use the `tk "wm deiconify ."` command. It is also common practice to use `wm withdraw` and `wm deiconify` while creating the widgets of an application, in order to reduce “flickering”.

- Instead of calling `tk_main`, you can also code your own main loop in Pure as follows:

  ```pure
  main = do_something $$ main if tk_ready;
    = () otherwise;
  ```

  Note that the `tk_ready` function checks whether the Tcl interpreter is still up and running, after processing any pending events in the interpreter. This setup allows you to do your own custom idle processing in Pure while the application is running. However, you have to be careful that your `do_something` routine runs neither too short nor too long (a few milliseconds should usually be ok). Otherwise your main loop may turn into a busy loop and/or the GUI may become very sluggish and unresponsive.
Thus it’s usually better to just call `tk_main` and do any necessary background processing using the Tcl interpreter’s own facilities (e.g., by setting up a Pure callback with the `Tcl after command`).

- The `tk` function can become rather tedious when coding larger Tk applications. Usually, you will prefer to put the commands making up your application into a separate Tcl script. One way to incorporate the Tcl script into your your Pure program is to use the `Tcl source` command, e.g.:

  tk "source myapp.tcl";

However, this always requires the script to be available at runtime. Another method is to read the script into a string which is assigned to a Pure constant, and then invoke the `tk` command on this string value:

```
using system;
const ui = fget $ fopen "myapp.tcl" "r";
tk ui;
```

This still reads the script at runtime if the Pure program is executed using the Pure interpreter. However, you can now compile the Pure program to a native executable (see the Pure manual for details on this), in which case the text of the Tcl script is included verbatim in the executable. The compiled program can then be run without having the original Tcl script file available:

```
$ pure -c myapp.pure -o myapp
$ ./myapp
```

This is also the method to use for running existing Tk applications, e.g., if you create the interface using some interface builder like `vtcl`.

- The Tcl `package` command allows you to load additional extensions into the Tcl interpreter at runtime. For instance:

  tk "package require Gnocl";

This loads Peter G. Baum’s `Gnocl` extension which turns Tcl into a frontend for GTK+ and Gnome. In fact, pure-tk includes a special module to handle the nitty-gritty details of creating a GTK+/Gnome application from a Glade UI file and set up Pure callbacks as specified in the UI file. To use this, just import the `gnocl.pure` module into your Pure scripts:

```
using gnocl;
```

Note that the Glade interface requires that you have a fairly recent version of Gnocl installed (Gnocl 0.9.94g has been tested). The other facilities provided by the `gnocl.pure` module should also work with older Gnocl versions such as Gnocl 0.9.91. Please see the `gnocl.pure` module and the corresponding examples included in the sources for more information.

- The Tcl `exit` procedure, just as in `tclsh` or `wish`, causes exit from the current process. Since the Tcl interpreter hosted by the `pure-tk` module runs as part of a Pure program
and not as a separate child process, this might not be what you want. If you’d like exit to only exit the Tcl interpreter, without exiting the Pure program, you can redefine the exit procedure, e.g., as follows:

```
tk "proc exit { {returnCode 0} } { pure tk.quit }";
```

If you want to do something with the exit code provided by exit, you will have to provide an appropriate callback function, e.g.:

```
tk "proc exit { {returnCode 0} } { pure quit_cb $returnCode }";
```

A suitable implementation of `quit_cb` might look as follows:

```
quit_cb 0 = puts "Application exited normally." $$ tk.quit;
quit_cb n = printf "Application exited with exit code %d.\n" n $$
        tk.quit otherwise;
```

- If you need dialogs beyond the standard kinds of message boxes and common dialogs, you will have to do these yourself using a secondary toplevel. The dialog toplevel is just like the main window but will only be shown when the application needs it. You can construct both non-modal and modal dialogs this way, the latter can be implemented using Tk’s `grab` command.
faust2pd: Pd Patch Generator for Faust

Version 2.16, April 11, 2018
Albert Graef <aggraef@gmail.com>

This package contains software which makes it easier to use Faust DSPs with Pd and the Pure programming language. The main component is the faust2pd script which creates Pd GUI wrappers for Faust DSPs. The package also includes a Pure script faustxml.pure for parsing Faust dsp descriptions in XML or JSON format, as well as a bunch of examples. The software is distributed under the GPL; see the COPYING file for details.

**Note:** This faust2pd version is written in Pure and was ported from an earlier version written in Pure’s predecessor Q. The version of the script provided here should be 100% backward-compatible to those previous versions, except for the following changes:

- The (rarely used) \(-f\) (a.k.a. \(--fake-buttons\)) option was renamed to \(-b\), and a new \(-f\) (a.k.a. \(--font-size\)) option was added to change the font size of the GUI elements.

- For compatibility with pd-faust, the \(-s\) (a.k.a. \(--slider-nums\)) flag is enabled by default now. The corresponding option is still supported for backward compatibility, and for overriding the new \(--no-slider-nums\) option which can be used to disable this feature.

- Most command line options can now also be specified using special meta data in the Faust source.

As of version 2.1, the faust2pd script is now compiled to a native executable before installation. This makes the program start up much faster, which is a big advantage because most xml and json files don’t take long to be processed.

faust2pd version 2.11 and later have full support for Faust’s new JSON-based description format, which is generated with the \(-json\) option. The JSON-based interface offers some advantages, such as accessing additional meta data in the Faust source (the XML format doesn’t offer this in the latest Faust versions any more), and the capability to read dsp descriptions straight from running dsp instances in httpd-enabled Faust applications and Grame’s new
FaustLive environment. However, this format is only supported in the latest Faust versions (Faust 0.9.70 and later, or Faust 2.0.a30 and later if you are running the Faust2 development version). At the time of this writing, these versions are only available in the Faust git repository.

31.1 Copying

Copyright (c) 2009-2017 by Albert Graef.

faust2pd is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

faust2pd is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

31.2 Requirements

faust2pd is known to work on Linux, Mac OS X, and Windows, and there shouldn’t be any major roadblocks preventing it to work on other systems supported by Pure.

The faust2pd script is written in the Pure programming language and requires Pure’s XML module, so you need to install these to make it work. Install the latest pure*.tar.gz and pure-xml*.tar.gz packages and you should be set. (Pure 0.47 or later is required.) Also make sure that the LLVM base package is installed, as described in the Pure INSTALL file, some LLVM utilities are needed to make Pure’s batch compiler work.

To run the seqdemo example, you’ll also need the Pd Pure external (pd-pure*.tar.gz), also available at the Pure website.

To compile the examples, you’ll need GNU C++ and make, Pd and, of course, Faust. Make sure you get a recent version of Faust; Faust 0.9.67 or later is required. Faust 0.9.70 and later have support for the new JSON format and offer some other new and convenient capabilities, such as retrieving the JSON description directly from a running dsp instance via Faust’s httpd interface; for the latter, you also need to have the curl program installed. Note that the examples still use the “old” a.k.a. “legacy” Faust library modules, so they should work out of the box with both “old” Faust versions (up to 0.9.85) and later ones featuring the “new” Faust library (anything after 0.9.85, including current git sources).

31.3 Installation

Run `make` and `make install` to compile and install the faust2pd program on your system. You can set the installation prefix by running `make install prefix=/some/path`. Default installation prefix is `/usr/local`, faust2pd is installed in the bin directory below that.

Optionally, you can also run `make install-pd` to copy the supporting Pd abstractions (faust-*.pd) to your lib/pd/extra directory, so that you can use the patches generated by faust2pd without copying these abstractions to your working directory. The Makefile tries to guess the prefix of your Pd installation, if it guesses wrong, you can specify the prefix explicitly by running `make install-pd pdprefix=/some/path`.

The included faustxml.pure script provides access to Faust-generated dsp descriptions in XML or JSON files to Pure scripts. This module is described in its own appendix below. It may have uses beyond faust2pd, but isn’t normally installed. If you want to use this module, you can just copy it to your Pure library directory.

### 31.4 Quickstart

Run `make examples` to compile the Faust examples included in this package to corresponding Pd plugins. After that you should be able to run the patches in the various subdirectories of the examples directory. Everything is set up so that you can try the examples “in-place”, without installing anything except the required software as noted in Requirements above. You can also run `make realclean` before `make` to regenerate everything from scratch (this requires faust2pd, so this will only work if you already installed the Pure interpreter).

Faust Pd plugins work in much the same way as the well-known plugin~ object (which interfaces to LADSPA plugins), except that each Faust DSP is compiled to its own Pd external. Under Linux, the basic compilation process is as follows (taking the freeverb module from the Faust distribution as an example):

```bash
# compile the Faust source to a C++ module using the "puredata" architecture
faust -a puredata.cpp freeverb.dsp -o freeverb.cpp

# compile the C++ module to a Pd plugin
cc -shared -Dmydsp=freeverb freeverb.cpp -o freeverb~.pd_linux
```

By these means, a Faust DSP named `xyz` with n audio inputs and m audio outputs becomes a Pd object `xyz~` with n+1 inlets and m+1 outlets. The leftmost inlet/outlet pair is for control messages only. This allows you to inspect and change the controls the unit provides, as detailed below. The remaining inlets and outlets are the audio inputs and outputs of the unit, respectively. For instance, `freeverb.dsp` becomes the Pd object `freeverb~` which, in addition to the control inlet/outlet pair, has 2 audio inputs and outputs.

When creating a Faust object it is also possible to specify, as optional creation parameters, an extra unit name (this is explained in the following section) and a sample rate. If no sample rate is specified explicitly, it defaults to the sample rate at which Pd is executing. (Usually it is not necessary or even desirable to override the default choice, but this might occasionally be useful for debugging purposes.)

As already mentioned, the main ingredient of this package is a Pure script named “faust2pd” which allows you to create Pd abstractions as “wrappers” around Faust units. The wrappers generated by faust2pd can be used in Pd patches just like any other Pd objects. They are
much easier to operate than the “naked” Faust plugins themselves, as they also provide “graph-on-parent” GUI elements to inspect and change the control values.

The process to compile a plugin and build a wrapper patch is very similar to what we’ve seen above. You only have to add the -xml option when invoking the Faust compiler and run faust2pd on the resulting XML file:

```
# compile the Faust source and generate the xml file
faust -a puredata.cpp -xml freeverb.dsp -o freeverb.cpp
# compile the C++ module to a Pd plugin
g++ -shared -Dmydsp=freeverb freeverb.cpp -o freeverb~.pd_linux
# generate the Pd patch from the xml file
faust2pd freeverb.dsp.xml
```

As of version 2.11, faust2pd can also process dsp descriptions in Faust’s new JSON format (-json option). Please see Wrapping DSPs with faust2pd below for further details.

Note that, just as with other Pd externals and abstractions, the compiled .pd_linux modules and wrapper patches must be put somewhere where Pd can find them. To these ends you can either move the files into the directory with the patches that use the plugin, or you can put them into the lib/pd/extra directory or some other directory on Pd’s library path for system-wide use.

Also, faust2pd-generated wrappers use a number of supporting abstractions (the faust-*.pd files in the faust2pd sources), so you have to put these into the directory of the main patch or install them under lib/pd/extra as well. (The make pd-install step does the latter, see Installation above.)

### 31.5 Control Interface

The control inlet of a Faust plugin understands messages in one of the following forms:

- **bang**, which reports all available controls of the unit on the control outlet, in the form:  
  
  ```
  type name val init min max step
  ```
  
  where type is the type of the control as specified in the Faust source (checkbox, nentry, etc.), name its (fully qualified) name, val the current value, and init, min, max, step the initial value, minimum, maximum and stepsize of the control, respectively.

- **foo 0.99**, which sets the control foo to the value 0.99, and outputs nothing.

- Just **foo**, which outputs the (fully qualified) name and current value of the foo control on the control outlet.

Control names can be specified in their fully qualified form, like e.g. `/gnu/bar/foo` which indicates the control foo in the subgroup bar of the topmost group gnu, following the hierarchical group layout defined in the Faust source. This lets you distinguish between different controls with the same name which are located in different groups. To find out about all the controls of a unit and their fully qualified names, you can bang the control inlet of the unit as described above, and connect its control outlet to a print object, which will cause the descriptions of all controls to be printed in Pd’s main window. (The same information can
also be used, e.g., to initialize GUI elements with the proper values. Patches generated with faust2pd rely on this.)

You can also specify just a part of the control path (like bar/foo or just foo in the example above) which means that the message applies to all controls which have the given pathname as the final portion of their fully qualified name. Thus, if there is more than one foo control in different groups of the Faust unit then sending the message foo to the control inlet will report the fully qualified name and value for each of them. Likewise, sending foo 0.99 will set the value of all controls named foo at once.

Concerning the naming of Faust controls in Pd you should also note the following:

- A unit name can be specified at object creation time, in which case the given symbol is used as a prefix for all control names of the unit. E.g., the control /gnu/bar/foo of an object baz~ created with baz~ baz1 has the fully qualified name /baz1/gnu/bar/foo. This lets you distinguish different instances of an object such as, e.g., different voices of a polyphonic synth unit.

- Pd’s input syntax for symbols is rather restrictive. Therefore group and control names in the Faust source are mangled into a form which only contains alphanumeric characters and hyphens, so that the control names are always legal Pd symbols. For instance, a Faust control name like meter #1 (dB) will become meter-1-dB which can be input directly as a symbol in Pd without any problems.

- “Anonymous” groups and controls (groups and controls which have empty labels in the Faust source) are omitted from the path specification. E.g., if foo is a control located in a main group with an empty name then the fully qualified name of the control is just /foo rather than //foo. Likewise, an anonymous control in the group /foo/bar is named just /foo/bar instead of /foo/bar/.

Last but not least, there is also a special control named active which is generated automatically for your convenience. The default behaviour of this control is as follows:

- When active is nonzero (the default), the unit works as usual.
- When active is zero, and the unit’s number of audio inputs and outputs match, then the audio input is simply passed through.
- When active is zero, but the unit’s number of audio inputs and outputs do not match, then the unit generates silence.

The active control frequently alleviates the need for special “bypass” or “mute” controls in the Faust source. However, if the default behaviour of the generated control is not appropriate you can also define your own custom version of active explicitly in the Faust program; in this case the custom version will override the default one.

### 31.6 Examples

In the examples subdirectory you’ll find a bunch of sample Faust DSPs and Pd patches illustrating how Faust units are used in Pd.
• The examples/basic/test.pd patch demonstrates the basics of operating “bare” Faust plugins in Pd. You’ll rarely have to do this when using the wrappers generated with the faust2pd program, but it is a useful starting point to take a look behind the scenes anyway.

• The examples/faust directory contains all the examples from (an earlier version of) the Faust distribution, along with corresponding Pd wrappers generated with faust2pd. Have a look at examples/faust/faustdemo.pd to see some of the DSPs in action. Note that not all examples from the Faust distribution are working out of the box because of name clashes with Pd builtins, so we renamed those. We also edited some of the .dsp sources (e.g., turning buttons into checkboxes or sliders into nentries) where this seemed necessary to make it easier to operate the Pd patches.

• The examples/synth directory contains various plugins and patches showing how to implement polyphonic synthesizers using Faust units. Take a look at examples/synth/synth.pd for an example. If you have properly configured your interfaces then you should be able to play the synthesizer via Pd’s MIDI input.

• The examples/seqdemo/seqdemo.pd patch demonstrates how to operate a multitimbry synth, built with Faust units, in an automatic fashion using a pattern sequencer programmed in Pure. This example requires the Pure interpreter as well as the pd-pure plugin available from https://agraef.github.io/pure-lang/.

31.7 Wrapping DSPs with faust2pd

The faust2pd script generates Pd patches from the dsp.xml files created by Faust when run with the -xml option. Most of the sample patches were actually created that way. After installation you can run the script as follows:

```
faust2pd [-hVbs] [-f size] [-o output-file] [-n #voices]
[-r max] [-X patterns] [-x width] [-y height] input-file
```

The default output filename is `input-file` with new extension `.pd`. Thus, `faust2pd filename.dsp.xml` creates a Pd patch named `filename.pd` from the Faust XML description in `filename.dsp.xml`.

31.7.1 JSON Support

As of version 2.11, faust2pd also fully supports Faust’s new JSON-based description format, which is generated with the -json option. In this case the filename extension is `.dsp.json`, so `faust2pd` is invoked as `faust2pd filename.dsp.json` instead. Please note that this format is only supported in the latest Faust versions (Faust 0.9.70 and later).

Instead of generating a JSON file with the Faust compiler, you can also read the JSON description straight from a running dsp instance via the httpd interface. This works with both stand-alone Faust applications which have the httpd interface enabled (e.g., created with `faust2jaqt -httpd mydsp.dsp`) and instances running in Grame’s FaustLive application. To these ends, you just specify the URL of the running dsp instance instead of the JSON filename. (To make this work, you need to have `curl` installed.)
For instance, assuming that there’s a Faust dsp running locally at port 5510, you can run faust2pd as follows to create a GUI patch for it: `faust2pd http://localhost:5510`. You can find out about the port a Faust dsp runs on by inspecting the terminal output of a stand-alone Faust application. In FaustLive, use the Window / View QRcode menu option to retrieve the IP under which the httpd interface of a dsp window can be accessed. If FaustLive is running locally on its default port (7777), then you can also retrieve a list of dsp instances currently running in FaustLive using `faust2pd http://localhost:7777/availableInterfaces`. This prints the dsp names along with their URLs on stdout.

### 31.7.2 faust2pd Options

The faust2pd program understands a number of options which affect the layout of the GUI elements and the contents of the generated patch. Here is a brief list of the available options:

- `-h, --help` display a short help message and exit
- `-V, --version` display the version number and exit
- `-b, --fake-buttons` replace buttons (bangs) with checkboxes (toggles)
- `-f, --font-size` font size for GUI elements (10 by default)
- `-n, --nvoices` create a synth patch with the given number of voices
- `-o, --output-file` output file name (.pd file)
- `-r, --radio-sliders` radio controls for sliders
- `-s, --slider-nums` sliders with additional number control
- `-X, --exclude` exclude controls matching the given glob patterns
- `-x, --width` maximum width of the GUI area
- `-y, --height` maximum height of the GUI area

Just like the Faust plugin itself, the generated patch has a control input/output as the leftmost inlet/outlet pair, and the remaining plugs are signal inlets and outlets for each audio input/output of the Faust unit. However, the control inlet/outlet pair works slightly different from that of the Faust plugin. Instead of being used for control replies, the control outlet of the patch simply passes through its control input (after processing messages which are understood by the wrapped plugin). By these means control messages can flow along with the audio signal through an entire chain of Faust units. (You can find an example of this in examples/faust/faustdemo.pd.) Moreover, when generating a polyphonic synth patch using the `-n` option then there will actually be two control inlets, one for note messages and one for ordinary control messages; this is illustrated in the examples/synth/synth.pd example.

The generated patch also includes the necessary GUI elements to see and change all (active and passive) controls of the Faust unit. Faust control elements are mapped to Pd GUI elements in an obvious fashion, following the horizontal and vertical layout specified in the Faust source. The script also adds special buttons for resetting all controls to their defaults and to operate the special active control.
This generally works very well, but the control GUIs generated by faust2pd are somewhat hampered by the limited range of GUI elements available in a vanilla Pd installation. As a remedy, faust2pd provides various options to change the content of the generated wrapper and work around these limitations.

- There are no real button widgets as required by the Faust specification, so bangs are used instead. There is a global delay time for switching the control from 1 back to 0, which can be changed by sending a value in milliseconds to the `faust-delay` receiver. If you need interactive control over the switching time then it is better to use checkboxes instead, or you can have faust2pd automatically substitute checkboxes for all buttons in a patch by invoking it with the -b a.k.a. -fake-buttons option.

- Sliders in Pd do not display their value in numeric form so it may be hard to figure out what the current value is. Therefore faust2pd has an option -s a.k.a. -slider-nums which causes it to add a number box to each slider control. (This flag also applies to Faust’s passive bargraph controls, as these are implemented using sliders, see below. As of faust2pd 2.12, this option is actually the default now, but you can still disable it with the –no-slider-nums option.)

- Pd’s sliders also have no provision for specifying a stepsize, so they are an awkward way to input integral values from a small range. OTOH, Faust doesn’t support the “radio” control elements which Pd provides for that purpose. As a remedy, faust2pd allows you to specify the option -r max (a.k.a. –radio-sliders=max) to indicate that sliders with integral values from the range 0..max-1 are to be mapped to corresponding Pd radio controls.

- Faust’s bargraphs are emulated using sliders. Note that these are passive controls which just display a value computed by the Faust unit. A different background color is used for these widgets so that you can distinguish them from the ordinary (active) slider controls. The values shown in passive controls are sampled every 40 ms by default. You can change this value by sending an appropriate message to the global `faust-timer` receiver.

- Since Pd has no “tabbed” (notebook-like) GUI element, Faust’s tgroups are mapped to hgroups instead. It may be difficult to present large and complicated control interfaces without tabbed dialogs, though. As a remedy, you can control the amount of horizontal or vertical space available for the GUI area with the -x and -y (a.k.a. –width and –height) options and faust2pd will then try to break rows and columns in the layout to make everything fit within that area. (This feature has only been tested with simple layouts so far, so beware.)

- You can also exclude certain controls from appearing in the GUI using the -X option. This option takes a comma-separated list of shell glob patterns indicating either just the names or the fully qualified paths of Faust controls which are to be excluded from the GUI. For instance, the option -X ‘volume,meter*,faust/resonator*/’ will exclude all volume controls, all controls whose names start with meter, and all controls in groups matching faust/resonator. (Note that the argument to -X has to be quoted if it contains any wildcards such as * and ?, so that the shell doesn’t try to expand the patterns beforehand. Also note that only one -X option is recognized, so you have to specify all controls to be excluded as a single option.)
• Faust group labels are not shown at all, since I haven’t found an easy way to draw
some kind of labelled frame in Pd yet.

Despite these limitations, faust2pd appears to work rather well, at least for the kind of DSPs
found in the Faust distribution. (Still, for more complicated control surfaces and interfaces
to be used on stage you’ll probably have to edit the generated GUI layouts by hand.)

For convenience, all the content-related command line options mentioned above can also be
specified in the Faust source, as special meta data in the label of the toplevel group of the
dsp. These take the form [pd:option] or [pd:option=value] where option is any of the
layout options understood by faust2pd. For instance:

process = vgroup("mysynth [pd:nvoices=8] [pd:no-slider-nums]", ...);

Alternatively, as of faust2pd 2.11, these options can also be specified as a single chunk of
global meta data, using the faust2pd key. So the above can also be written as:

declare faust2pd "--nvoices=8 --no-slider-nums";

Note that source options carrying arguments, like --nvoices in the above example, can still
be overridden with corresponding command line options. Also note that all this works with
the JSON format only, as meta data in the Faust source isn’t recorded in the XML format
produced by recent Faust versions any more.

31.8 Conclusion

Creating Faust plugins for use with Pd has never been easier before, so I hope that you’ll
soon have much joy trying your Faust programs in Pd. Add Pd-Pure to this, and you can
program all your specialized audio and control objects using two modern-style functional
languages which are much more fun than C/C++. Of course there’s an initial learning curve
to be mastered, but IMHO it is well worth the effort. The bottomline is that Pd+Faust+Pure
really makes an excellent combo which provides you with a powerful, programmable in-
teractive environment for creating advanced computer music and multimedia applications
with ease.

31.8.1 Acknowledgements

Thanks are due to Yann Orlarey for his wonderful Faust, which makes developing DSP
algorithms so easy and fun.

31.9 Appendix: faustxml

The faustxml module is provided along with faust2pd to retrieve the description of a Faust
DSP from its XML or JSON file as a data structure which is ready to be processed by Pure
programs. It may also be useful in other Pure applications which need to inspect descriptions
of Faust DSPs.

The main entry point is the info function which takes the name of a Faust-generated XML or
JSON file as argument and returns a tuple (name, descr, version, in, out, controls,
options) with the name, description, version, number of inputs and outputs, control descriptions and faust2pd options (from the global meta data of the dsp module). A couple of other convenience functions are provided to deal with the control descriptions.

### 31.9.1 Usage

Use the following declaration to import this module in your programs:

```cpp
using faustxml;
```

For convenience, you can also use the following to get access to the module’s namespace:

```cpp
using namespace faustxml;
```

### 31.9.2 Data Structure

The following constructors are used to represent the UI controls of Faust DSPs:

- `constructor faustxml::button label`  
  A button or checkbox with the given label.

- `constructor faustxml::checkbox label`  
  Similar to button.

- `constructor faustxml::nentry (label,init,min,max,step)`  
  A numeric input control with the given label, initial value, range and stepwidth.

- `constructor faustxml::vslider (label,init,min,max,step)`  
  A numeric input control with the given label, initial value, range and stepwidth.

- `constructor faustxml::hslider (label,init,min,max,step)`  
  A numeric input control with the given label, initial value, range and stepwidth.

- `constructor faustxml::vbargraph (label,min,max)`  
  A numeric output control with the given label and range.

- `constructor faustxml::hbargraph (label,min,max)`  
  Similar to vbargraph.

- `constructor faustxml::vgroup (label,controls)`  
  A group with the given label and list of controls in the group.

- `constructor faustxml::hgroup (label,controls)`  
  Similar to vgroup.

- `constructor faustxml::tgroup (label,controls)`  
  Similar to vgroup.

### 31.9.3 Operations

- `faustxml::control p x`  
  Check for control description values.

- `faustxml::control_type x`  
- `faustxml::control_label x`  
- `faustxml::control_args x`  
  Access functions for the various components of a control description.

- `faustxml::controls x`  
  This function returns a flat representation of a control group x as a list of basic control descriptions, which provides a quick way to access all the control values of a Faust DSP. The grouping controls themselves are omitted. You can pass the last component of the return value of the `info` function to this function.
faustxml::pcontrols

Works like the controls function above, but also replaces the label of each basic control with a fully qualified path consisting of all control labels leading up to the given control. Thus, e.g., the label of a slider "gain" inside a group "voice#0" inside the main "faust" group will be denoted by the label "faust/voice#0/gain".

faustxml::info fname

Extract the description of a Faust DSP from its XML or JSON file. This is the main entry point. Returns a tuple with the name, description and version of the DSP, as well as the number of inputs and outputs, the toplevel group with all the control descriptions, and additional faust2pd-specific options specified in the global meta data. Raises an exception if the XML/JSON file doesn't exist or contains invalid contents.

Example:

```
> using faustxml;
> let name, descr, version, in, out, group, opts =
>   faustxml::info "examples/basic/freeverb.dsp.xml";
> name, descr, version, in, out;
"freeverb", "freeverb -- a Schroeder reverb", "1.0", 2, 2
> using system;
> do (puts.str) $ faustxml::pcontrols group;
faustxml::hslider ("freeverb/damp", 0.5, 0.0, 1.0, 0.025)
faustxml::hslider ("freeverb/roomsize", 0.5, 0.0, 1.0, 0.025)
faustxml::hslider ("freeverb/wet", 0.3333, 0.0, 1.0, 0.025)
```

Note: As of faust2pd 2.11, the info function can also process descriptions in JSON format (as obtained with faust -json in recent Faust versions). Moreover, instead of a JSON file you may also specify the URL of a running Faust dsp instance (typically something like http://localhost:5518). This works with stand-alone Faust applications which have httpd support enabled (created with, e.g., faust2jaqt -httpd), as well as dsp instances running in Grame’s FaustLive application. You also need to have the curl program installed to make this work.

The latter currently has some minor limitations. Specifically, the httpd/JSON interface only provides the name of a running dsp; the description, version and other global meta data is not available. In the current implementation, we therefore set the description to the name of the dsp, and the version and auxiliary faust2pd options to empty strings in this case.

Furthermore, the info function can also be invoked with a special URL of the form http://localhost:7777/availableInterfaces to retrieve the list of dsp instances running in a (local or remote) FaustLive instance. (Replace localhost with the hostname or IP address and 7777 with the actual port number as necessary. FaustLive’s default port is usually 7777, but you should check the actual IP address with FaustLive’s Window / View QRcode option.) The result is a list of hash pairs of names and URLs of dsp instances which can be queried for their JSON data.
pd-faust

Version 0.18, October 31, 2018

Albert Graef <aggraef@gmail.com>

pd-faust is a dynamic environment for running Faust dsps in Pd. It is based on the author’s faust2pd script, but offers many small improvements and some major additional features:

- Faust dsps are implemented by the faust~ external which provides the necessary infrastructure to run Faust instruments and effect units in Pd.

- In contrast to faust2pd, the Pd GUI of Faust units is generated dynamically, inside Pd. While pd-faust supports the same global GUI layout options as faust2pd, it also provides various options to adjust the layout of individual control items.

- pd-faust recognizes the midi and osc controller attributes in the Faust source and automatically provides corresponding MIDI and OSC controller mappings. OSC-based controller automation is also available through a separate helper abstraction.

- Perhaps most importantly, Faust dsps can be reloaded at any time (even while the Pd patch is running), in which case the GUI and the controller mappings are regenerated automatically and on the fly as needed.

32.1 Copying

Copyright (c) 2011-2018 by Albert Graef

pd-faust is distributed under the GNU LGPL v3+. Please see the included COPYING and COPYING.LESSER files for details.

This package also includes the faust-stk instruments which are distributed under an MIT-style license, please check the examples/dsp/README-STK file and the dsp files for authorship information and licensing details pertaining to these. The original faust-stk sources can be found in the Faust distribution, cf. http://faust.grame.fr/.

785
32.2 Installation

You’ll need Faust and Pd, obviously. Faust versions >= 0.9.46 and 2.0.a3 and Pd version >= 0.43.1 have been tested and are known to work. Note that the examples still use the “old” a.k.a. “legacy” Faust library modules, so they should work out of the box with both “old” Faust versions (up to 0.9.85) and later ones featuring the “new” Faust library (anything after 0.9.85, including current git sources).

The pd-faust objects are written in the Pure programming language, so you’ll also need an installation of the Pure interpreter (0.51 or later), along with the following packages (minimum required versions are given in parentheses): pd-pure (0.26), pure-faust (0.8), pure-midi (0.5) and pure-stldict (0.3).

Finally, gcc and GNU make (or compatible) are required to compile the helper dsps and the example instruments; please check the Makefile for details.

For a basic installation run make, then sudo make install. This will install the pd-faust objects in your lib/pd/extra/faust folder as a Pd object library which can be loaded with Pd’s -lib option. To complete the installation, you still have to make sure that the library is loaded automatically at startup. This is done most conveniently by adding faust/pdfaust to your preloaded library modules in Pd’s Preferences/Startup dialog.

Note: The faust/pdfaust module must come after the pure entry which loads pd-pure, otherwise you’ll get an error message. In any case the pd-pure loader will be required to run these objects, so it should be configured accordingly; please check the pd-pure documentation for details.

The make command also compiles the Faust dsps included in the distribution, so that the provided examples will be ready to run afterwards well (see Examples below).

The Makefile tries to guess the installation prefix under which Pd is installed. If it guesses wrong, you can tell it the right prefix with make prefix=/some/path. Or you can specify the exact path of the lib/pd directory with make pdlibdir=/some/path; by default the Makefile assumes $(prefix)/lib/pd.

It is also possible to specify an alternative flavour of Pd when building and installing the module, by adding a definition like PD=pd-extended to the make command line. This is known to work with pd-extended and pd-l2ork, two popular alternative Pd distributions available on the web, as well as purr-data (the new cross-platform version of pd-l2ork).

Some further build options are described in the Makefile. In particular, it is possible to compile the Faust dsps to LLVM bitcode which can be loaded directly by the Pure interpreter. This requires a recent Faust version (2.0 and later) and an LLVM-capable C/C++ compiler such as clang (please check the Compiling Faust DSPs section below for details). If you have the required tools then you can build the bitcode modules by running make bitcode after make. If you run make install afterwards, the bitcode modules will be installed along with the “normal” Faust plugins. In addition, a second object library called pdfaust2 will be built and installed, which can be used as a drop-in replacement for pdfaust and lets you run the bitcode modules. (Note that in the present implementation it is not possible to load both
32.3 Usage

Working with pd-faust basically involves adding a bunch of faust~ objects to a Pd patch along with the corresponding GUI subpatches, and wiring up the Faust units in some variation of a synth-effects chain which typically takes input from Pd’s MIDI interface (notein, ctlin, etc.) and outputs the signals produced by the Faust units to Pd’s audio interface (dac~).

For convenience, pd-faust also includes a few helper objects and abstractions to handle MIDI input and playback as well as OSC controller automation. For simple uses, the included midi-input and midi-output abstractions provide a way to encode and decode MIDI messages in the author’s SMMF format used by faust~ objects. For applications requiring more elaborate MIDI and OSC support, the midiseq and oscseq objects and a corresponding midiosc abstraction can be used to handle MIDI input and playback as well as OSC controller automation. This is described in more detail under MIDI and OSC Sequencing below.

pd-faust interprets MIDI, OSC and Faust dsp filenames relative to the hosting Pd patch by default. It will also search the midi, osc and dsp subfolders, if they exist, for the corresponding types of files. Failing that, it finally searches the directories on the Pd library path (including their midi, osc and dsp subfolders). To disable this search, just use absolute pathnames (or pathnames relative to the . or .. directory) instead.

Like pd-pure, pd-faust remaps Pd’s menu-open command so that it lets you edit the Faust source of a faust~ object by right-clicking on the object and choosing Open from the context menu. (This requires that the .dsp source file of the Faust module is available in the same directory as the binary module.) There’s also special support for the Emacs editor which lets you quickly compile Faust programs and reload Faust dsps in Pd, see Remote Control for details.

32.3.1 Compiling Faust DSPs

To run a Faust module (.dsp file) inside Pd using the faust~ object, the Faust dsp must be compiled to a form which can be loaded in Pure (not Pd!), so the pure.cpp architecture (included in the Faust distribution) is used to compile the dsp to a shared library object. It is of course possible to do this manually using the faust and gcc compilers, but for convenience there’s a GNU Makefile in the examples/dsp subdirectory which provides all the build rules necessary to do this. This Makefile is self-contained, so you can just drop it into any directory with Faust dsp sources and run make there to compile the modules to a format which is ready to be loaded with pd-faust.

Another possibility is to use the faust2pure script included in recent Faust versions and also in the examples subdirectory of the pure-faust package, see the pure-faust documentation for details. E.g., to compile a Faust dsp organ.dsp to a module loadable with pd-faust, simply use the following command:
faust2pure organ.dsp

This will leave a shared library module organ.so (organ.dylib on macOS, organ.dll on Windows) in the current directory which can then be loaded with pd-faust, by just inserting an object like faust~ organ in your patch. Note that to make this work, pd-faust must be able to locate the object. To these ends, you should create the patch in the same directory that also contains the .dsp and .so files of the Faust dsp. (As mentioned earlier, it is also possible to put the .dsp and .so files into the dsp subdirectory of the directory containing the patch, or just put them somewhere on Pd’s library path.)

If you’re running a recent version of Faust, you can also compile to an LLVM bitcode file instead; pd-pure can load these directly using Pure’s built-in Faust bitcode loader. As already mentioned, this requires Faust 2.0 or later and that you build and install the alternative pdfaust2 library as described under Installation above. The main advantage of using bitcode modules is that compiling these is often much faster. The main disadvantage is that you’ll need a special C compiler capable of producing LLVM bitcode (i.e., clang).

The process of compiling Faust dsps to bitcode modules is pretty much the same as above, only that you have to run make bitcode with the provided Makefile, or use the faust2pure script with the -bitcode option, e.g.:

faust2pure -bitcode organ.dsp

This creates the organ.bc module which can be loaded by the pdfaust2 library, pretty much like pdfaust loads shared object modules. Otherwise there won’t be much of a noticeable difference (gcc may produce better code in some cases, clang in others, which may result in some Faust dsps running with better performance as shared library modules, others in bitcode). Note, however, that in the current implementation pdfaust and pdfaust2 can not be loaded at the same time in Pd, therefore you’ll have to decide beforehand which of the two available interfaces you want to use.

### 32.3.2 The faust~ Object

Starting with version 0.10, pd-faust offers the faust~ external which provides a uniform way to create both audio effects and synth (instrument) units, and also supplies reasonable defaults for most arguments. (While the underlying fdsp~ and fsynth~ objects of older pd-faust versions are still provided for backward compatibility, they are deprecated and shouldn’t be invoked directly any more.)

The faust~ object is invoked as follows:

faust~ dspname [instname] [channel] [numvoices]

The creation arguments in square brackets are optional. Please note that since the faust~ object is written in Pure, the creation arguments should be specified in Pure syntax. In particular, both dspname or instname may either be Pure identifiers or double-quoted strings (the former will automatically be translated to the latter). Similarly, the channel and numvoices arguments must be integer constants in Pure syntax, which is pretty much like Pd syntax but also allows the integer to be specified in hexadecimal, octal or binary.
The meaning of these arguments is as follows:

- **dspname** denotes the name of the Faust dsp (usually this is just the name of the .dsp file with the extension stripped off).

- **instname** denotes the name of the instance of the Faust unit. By default, this is the same as dspname. Multiple instances of the same Faust dsp can be used in a Pd patch, but then they must all have different instance names. The instance name is also used to identify the GUI subpatch of the unit (see below) and to generate unique OSC addresses for the unit’s control elements.

- **channel** is the number of the MIDI channel the unit responds to. This can be 1..16, or 0 (the default) to specify “omni” operation (listen to MIDI messages on all channels).

- **numvoices** denotes the number of voices of a synth unit. This determines the maximum number of notes which can be played simultaneously (i.e., the degree of polyphony). A numvoices value of zero can be used to indicate an effect unit. If the numvoices argument is omitted, the faust~ object checks the meta data of the Faust module to see whether the loaded Faust module is an effect or a synth, see below for details.

Note that if only a single number follows the dspname or instname argument then it is always interpreted as a channel number; thus, if you want to denote the numvoices value in the creation arguments then you’ll have to specify both channel and numvoices, in that order.

Unless specified explicitly, the number of voices of an instrument is determined using the value of the nvoices meta key declared in the dsp source. Thus, to turn a Faust dsp into a synth with 8 voices you can use a declaration like the following anywhere in the Faust program:

```faust
declare nvoices "8";
```

The format of this declaration is the same as for the faust-lv2 and faust-vst plugin architectures.

If the nvoices declaration isn’t present, the dsp is considered to be an effect unit by default. All default choices can be overridden by explicitly specifying the corresponding creation argument. In particular, you can specify the number of synth voices (overriding the nvoices key in the dsp source), or use a numvoices value of zero to force a synth to be loaded as an ordinary effect unit. Also, if there are multiple instances of the same dsp in a patch then you can (and should) explicitly specify different instance names using the instname argument, and the default channel value of zero (denoting omni input) can be overridden as needed if the unit should only listen on a specific MIDI channel.

### 32.3.3 Effect and Synth Units

A faust~ object with zero voices requires a Faust dsp which can work as an effect unit, processing audio input and producing audio output. The unit can have as many audio input and output channels as you like (including zero).

A faust~ object with a non-zero number of voices works in a similar fashion, but requires a Faust dsp which can work as a (monophonic) synthesizer. This typically means that the
unit has zero audio inputs and a nonzero number of audio outputs, although it is possible to have synths processing any number of audio input channels as well. (You can even have synths producing zero audio outputs, but this is generally not very useful.)

In the synth case, pd-faust also assumes that the Faust unit provides three so-called “voice controls” which indicate which note to play:

- **freq** is the fundamental frequency of the note in Hz.
- **gain** is the velocity of the note, as a normalized value between 0 and 1. This usually controls the volume of the output signal.
- **gate** indicates whether a note is currently playing. This value is either 0 (no note to play) or 1 (play a note), and usually triggers the envelop function (ADSR or similar).

pd-faust doesn’t care at which path inside the Faust dsp these controls are located, but they must all be there, and the basenames of the controls must be unique throughout the entire dsp. Otherwise the synth will not work as expected.

Like *faust2pd*, pd-faust implements the necessary logic to drive the given number of voices of a *faust~* instrument object. That is, it will actually create a separate instance of the Faust dsp for each voice and handle polyphony by allocating voices from this pool in a round-robin fashion, performing the usual voice stealing if the number of simultaneous notes to play exceeds the number of voices. Also note that a *faust~* instrument operated in omni mode (channel = 0) automatically filters out messages on channel 10 which is reserved for percussion in the General MIDI standard.

A *faust~* object always responds to the following messages:

- **bang** outputs the current control settings on the control outlet in OSC format.
- **write** outputs the current control settings to special midiout and oscout receivers, so that they can be processed and/or sent to external MIDI and/or OSC devices. This message can also be invoked with a numeric argument to toggle the “write mode” of the unit; please see External MIDI and OSC Controllers below for details.
- **reload** reloads the Faust unit. This also reloads the shared library or bitcode file if the unit was recompiled since the object was last loaded.
- **addr value** changes the control indicated by the OSC address addr. This is also used internally for communication with the Pd GUI and for controller automation.

The object also responds to MIDI controller messages of the form **ctl val num chan** and, in the case of instruments, note-related messages of the form **note num vel chan** (note on/off) and **bend val chan** (pitch bend). It also provides the necessary logic to map controller and note-related messages to the corresponding control changes in the Faust unit.

In addition, pd-faust 0.13 and later offer support for the MIDI Tuning Standard (MTS), so that instruments can be retuned using the corresponding sysex messages for octave-based tunings. To these ends, the *faust~* object accepts messages of the form **sysex b1 b2 ...** where b1, b2, ... are the individual data bytes of the message. A description of the MIDI Tuning Standard is beyond the scope of this manual. However, there are some tools which let you construct such messages from various input formats, such as the author’s *sclsyx*
program. You can then either include the tuning messages in a MIDI file or transmit them
directly to Pd’s MIDI input. There’s also a version of sclyx.pure included in the author’s pd-
smmf package, which can be run as a Pd external to output tunings in the format understood
by the faust~ object.

Each faust~ object also subscribes to the following three global receivers which enable you
to send various kinds of messages to all faust~ objects in a patch:

- faustdsp receives arbitrary messages. This is commonly used to distribute MIDI or
  OSC data to all Faust units in a patch, but can in fact be used to send any message
  recognized by faust~ objects.

- oscplay listens for OSC messages. In contrast to faustdsp, this receiver only recognizes
  OSC data, and is used, in particular, by the midiosc abstraction for OSC automation,
  see MIDI and OSC Sequencing below.

- reload can be used to reload all faust~ units in a patch. This receiver accepts any input
  message, so just sending a bang will do. (This is provided for backward compatibility
  with older pd-faust versions. You can also just send a reload message to the faustdsp
  receiver.)

Finally, faust~ objects also send a message of the form create instance or destroy
instance to the global faust-notify receiver whenever they are created and destroyed,
respectively. The argument indicates the instance name of the object being created or de-
stroyed. This receiver isn’t used by pd-faust itself in any way, but applications may receive
this symbol if they need to be notified about changes in the collection of loaded Faust units.

32.3.4 GUI Subpatches

For each faust~ object, the Pd patch may contain an (initially empty) “one-off” graph-on-
parent subpatch with the same name as the instance name of the Faust unit:

\texttt{pd instname}

You shouldn’t insert anything into this subpatch, its contents (a bunch of Pd GUI elements
 corresponding to the control elements of the Faust unit) will be generated automatically
by pd-faust when the corresponding faust~ object is created, and whenever the unit gets
reloaded at runtime.

As with faust2pd, the default appearance of the GUI can be adjusted in various ways; see
Tweaking the GUI Layout below for details.

The relative order in which you insert a faust~ object and its GUI subpatch into the main
patch matters. Normally, the GUI subpatch should be inserted first, so that it will be updated
automatically when its associated Faust unit is first created, and also when the main patch
is saved and then reloaded later.

However, in some situations it may be preferable to insert the GUI subpatch after its associ-
ated Faust unit. If you do this, the GUI will not be updated automatically when the main
patch is loaded, so you’ll have to reload the dsp manually (sending it a reload message) to
force an update of the GUI subpatch. This is useful, in particular, if you’d like to edit the
GUI patch manually after it has been generated.

In some cases it may even be desirable to completely “lock down” the GUI subpatch. This
can be done by simply renaming the GUI subpatch after it has been generated. When Pd
saves the main patch, it saves the current status of the GUI subpatches along with it, so that
the renamed subpatch will remain static and will never be updated, even if its associated
Faust unit gets reloaded. This generally makes sense only if the control interface of the
Faust unit isn’t changed after locking down its GUI patch. To “unlock” a GUI subpatch, you
just rename it back to its original name. (In this case you might also want to reintroduce the
Corresponding Faust unit afterwards, if you want to have the GUI generated automatically
without an explicit reload again.)

32.3.5 Examples

The examples folder contains a few example patches which illustrate how this all works.
Having compiled and installed pd-faust as described above, you can run these directly from
the examples directory in the sources, e.g.: pd test.pd. (You can also run the examples
without actually installing pd-faust if you invoke Pd from the main pd-faust source direc-
tory, e.g., as follows: pd -lib lib/pdfaust examples/test.pd.) The same collection of ex-
amples is also copied to $prefix/lib/pd/extra/faust when running make install (where
$prefix denotes the prefix under which Pd is installed, usually /usr or /usr/local) so that
you can also run them from there.

Here are some of the examples that are currently available:

- simple.pd: Minimalistic example which works without the midiosc abstraction.
- test.pd: Simple patch running a single Faust instrument.
- synth.pd: Slightly more elaborate patch featuring a synth-effects chain.
- bouree.pd: Full-featured example running various instruments.

For your convenience, related MIDI and OSC files as well as the Faust sources of the in-
struments and effects are contained in corresponding subdirectories (midi, osc, dsp) of the
examples directory. A slightly modified version of the faust-stk instruments from the Faust
distribution is also included, please check the examples/dsp/README-STK file for more
information about these. The MIDI files are all in standard MIDI file format. (Some of these
come from the faust-stk distribution, others can be found on the web.) The OSC files used
by pd-faust for controller automation are plain ASCII files suitable for hand-editing if you
know what you are doing; the format should be fairly self-explanatory.

32.3.6 Operating the Patches

The generated Pd GUI elements for the Faust dsps are pretty much the same as with faust2pd
(which see). The only obvious change is the addition of a “record” button (gray toggle in the
upper right corner) which enables recording of OSC automation data. This requires the
use of the midiosc abstraction which serves as a little sequencer applet that enables you to
control MIDI playback and OSC recording. The usage of this abstraction should be fairly obvious, but you can also find a brief description under MIDI and OSC Sequencing below.

Note that the `midiosc` abstraction, even though most of the distributed examples include it, is by no means required unless you really need the MIDI playback and OSC automation features it provides. In most simple use cases, you just insert `faust~` objects (along with their corresponding GUI subpatches if needed/wanted) into your patch, wire them up as needed and be done with it. If you also need MIDI input (controller and note data), the `midi-input` abstraction provides a simpler way to encode incoming MIDI messages from Pd’s MIDI inputs in the SMMF format understood by `faust~` objects. Simply connect the outlet of `midi-input` to the leftmost inlet of any `faust~` instrument or effect unit that you want to play or control through MIDI, make sure that the instrument (or last effect unit in the chain) is connected to Pd’s audio output a.k.a. `dac~`, and you should be set. MIDI output via the `midiout` receiver (cf. External MIDI and OSC Controllers) can be handled in a similar way using the `midi-output` abstraction (see simple.pd for an example).

32.3.7 MIDI and OSC Sequencing

Note: If you use the `midiosc` abstraction in your own patches, you should copy it to the directory containing your patch and other required files, so that MIDI and OSC files are properly located. Alternatively, you can also set up Pd’s search path as described at the beginning of the Usage section.

The first creation argument of `midiosc` is the name of the MIDI file, either as a Pure identifier (in this case the .mid filename extension is supplied automatically) or as a double-quoted string. Similarly, the second argument specifies the name of the OSC file. Both arguments are optional; if the second argument is omitted, it defaults to the name of the MIDI file with new extension .osc. You can also omit both arguments if neither MIDI file playback nor saving recorded OSC data is required. Or you can leave the first parameter empty (specify "" or 0 instead) to only set an OSC filename, if you don’t need MIDI playback. The latter is useful, in particular, if you use `midiosc` with an external MIDI sequencer (see below).

The abstraction has a single control outlet through which it feeds the generated MIDI and other messages to the connected `faust~` objects. Live MIDI input is also accepted and forwarded to the control outlet, after being translated to the format understood by `faust~` objects. In addition, `midiosc` can also be controlled through an external MIDI sequencer connected to Pd’s MIDI input. To these ends, MIDI Machine Control (MMC) can be used to start and stop OSC playback and recording with the transport controls of the external sequencer program. To make this work, the external sequencer must be configured as an MMC master.

At the bottom of the abstraction there is a little progress bar along with a time display which indicates the current song position. If playback is stopped, you can also use these to change the current position for playback, recording and a number of other operations as described below. Note that if you drive `midiosc` from an external MIDI sequencer instead, then it is a good idea to load the same MIDI file in `midiosc` anyway, so that it knows about the length of the MIDI sequence. This will make the progress bar display the proper position in the file.

Here is a brief rundown of the available controls:
• The start, stop and cont controls in the first row of control elements start, stop and continue MIDI and OSC playback, respectively. The midi toggle in this row causes played MIDI events to be printed in the Pd main window.

• The gray “record” toggle in the upper right corner of the abstraction enables recording of OSC controller automation data. Note that this toggle merely arms the OSC recorder; you still have to actually start the recording with the start button. However, you can also first start playback with start and then switch recording on and off as needed at any point in the sequence (this is also known as “punch in/out” recording). In either case, pushing the stop button stores the recorded sequence for later playback. Also note that before you can start recording any OSC data, you first have to arm the Faust units that you want to record. This is done with the “record” toggle in the Pd GUI of each unit.

• The “bang” button next to the “record” toggle lets you record a static snapshot of the current parameter settings of all armed units. This is also done automatically when starting a fresh recording. The “bang” button lets you change the starting defaults of parameters of an existing recording. It is also useful if you just want to record a static snapshot of the current parameter settings without recording any live parameter changes. Moreover, you can also set the parameters at any given point in the piece if you first position the progress bar or the time display accordingly; in this case you may first want to recall the parameter settings at the given point with the send button described below. In either case, recording must be enabled and playback must be off. Then just arm the Faust units that you wish to record, set the playback position as needed, change the controls to what you want their values to be (maybe after recalling the current settings), and finally push the “bang” button.

• There are some additional controls related to OSC recording in the second row: save saves the currently recorded data in an OSC file for later use; abort is like stop in that it stops recording and playback, but also throws away the data recorded in this take (rather than keeping it for later playback); and clear purges the entire recorded OSC sequence so that you can start a new one.

• Once some automation data has been recorded, it will be played back along with the MIDI file. You can then just listen to it, or go on to record more automation data as needed. Use the osc toggle in the second row to print the OSC messages as they are played back. If you save the automation data with the save button, it will be reloaded from its OSC file next time the patch is opened.

• The controls in the third row provide some additional ways to configure the playback process. The loop button can be used to enable looping, which repeats the playback of the MIDI (and OSC) sequence ad infinitum. The thru button, when switched on, routes the MIDI data during playback through Pd’s MIDI output so that it can be used to drive an external MIDI device in addition to the Faust instruments. The write button does the same with MIDI and OSC controller data generated either through automation data or by manually operating the control elements in the Pd GUI, see External MIDI and OSC Controllers below for details.

• There’s one additional button in the third row, the send button which recalls the recorded OSC parameter settings at a given point in the sequence. Playback must be
off for this to work. After setting the playback position as desired, just push the send button. This sets the controls to the current parameter values at the given point, for all parameters which have been recorded up to (and including) this point.

Please note that midiosc is merely a prototypical implementation which should cover most common uses. It can also be used as a starting point for your own abstractions if you need more elaborate input/output interfacing than what midiosc provides.

32.3.8 External MIDI and OSC Controllers

For instrument units, the faust~ object has built-in (and hard-wired) support for MIDI notes, pitch bend and MIDI controller 123 (all notes off). Other controller data received from external MIDI and OSC devices is interpreted according to the controller mappings defined in the Faust source (this is explained below), by updating the corresponding GUI elements and the control variables of the Faust dsp. (This only works with active Faust controls, i.e., dsp controls which are to be manipulated from the host environment, not the dsp’s passive a.k.a. “bargraph” controls which return control values computed by the dsp.)

A faust~ object can also be put in write mode by feeding a message of the form write 1 into its control inlet (the write 0 message disables write mode again). For convenience, the write toggle in the midiosc abstraction allows you to do this simultaneously for all Faust units connected to midiosc’s control outlet.

When an object is in write mode, it also outputs MIDI and OSC controller data in response to both automation data and the manual operation of the Pd GUI elements, again according to the controller mappings defined in the Faust source, so that it can drive an external device, e.g., in order to provide feedback to motorized MIDI or multitouch OSC controllers. This works with both active and passive Faust controls.

Note: For better or worse, the output is not emitted directly on the object’s control outlet, but instead goes to special midiout and oscout receivers provided by the midiosc abstraction which then takes care of outputting the data. Thus, if you’re not using midiosc, you will have to provide these receivers yourself if you want to process the generated MIDI and/or OSC data in some way (the included simple.pd example shows how to do this for MIDI data).

To configure MIDI controller assignments, the labels of the Faust control elements have to be marked up with the special midi attribute in the Faust source. For instance, a pan control (MIDI controller 10) may be implemented in the Faust source as follows:

\[
\text{pan} = \text{hslider}(\text{“pan [midi:ctrl 10]”}, 0, \cdot 1, 1, 0.01);
\]

pd-faust will then provide the necessary logic to handle MIDI input from controller 10 by changing the pan control in the Faust unit accordingly, mapping the controller values 0..127 to the range and step size given in the Faust source. Moreover, in write mode corresponding MIDI controller data will be generated and sent to the midiout receiver as discussed above, on the MIDI channel specified in the creation arguments of the Faust unit (0 meaning “omni”, i.e., output on all MIDI channels).
The same functionality is also available for external OSC devices, employing explicit OSC controller assignments in the Faust source by means of the osc attribute. E.g., the following enables input and output of OSC messages for the OSC /pan address:

```plaintext
pan = hslider("pan [osc:/pan]", 0, -1, 1, 0.01);
```

Note: In contrast to some other architectures included in the Faust distribution, at present pd-faust only allows literal OSC addresses (no glob-style patterns), and there is no way to specify an OSC value range (so the value ranges of the controls of an external OSC device must match the ranges of the corresponding controls in the Faust program).

To actually connect with external OSC devices, you will also need some OSC input and output facilities. Older versions of vanilla Pd didn’t offer these, and the built-in OSC facilities of the latest Pd versions still have some limitations, so pd-pure relies on 3rd party externals for that. We recommend Martin Peach’s OSC externals which are included in Hans-Christoph Steiner’s Pd-extended distribution and derivatives such as Pd-l2ork and Purr-Data.

pd-faust includes a version of the midiosc abstraction named midiosc-mrpeach which can be used as a drop-in replacement for midiosc and implements OSC input and output using Martin Peach’s objects. You most likely have to edit this abstraction to make it work for your local network setup; at least you’ll probably have to change the network addresses in the abstraction so that it works with the OSC device or application that you use.

Another useful abstraction is the oscbrowser object available in the author’s separate pd-mdnsbrowser package. It lets you discover and publish Zeroconf (Avahi/Bonjour) services in the local network, so that your Pd patches can establish OSC connections in an automatic fashion.

### 32.3.9 Tweaking the GUI Layout

As already mentioned, pd-faust provides the same global GUI layout options as faust2pd. Please check the faust2pd documentation for details. There are a few minor changes in the meaning of some of the options, though, which we consider notable improvements after some experience working with faust2pd. Here is a brief rundown of the available options, as they are implemented in pd-faust:

- `width=wd, height=ht`: Specify the maximum horizontal and/or vertical dimensions of the layout area. If one or both of these values are nonzero, pd-faust will try to make the GUI fit within this area.
- `font-size=sz`: Specify the font size (default is 10).
- `fake-buttons`: Render button controls as Pd toggles rather than bangs.
- `radio-sliders=max`: Render sliders with up to `max` different values as Pd radio controls rather than Pd sliders. Note that in pd-faust this option not only applies to sliders, but also to numeric entries, i.e., `nentry` in the Faust source. However, as with faust2pd’s `radio-sliders` option, the option is only applicable if the control is zero-based and has a stepsize of 1.
• **slider-nums**: Add a number box to each slider control. Note that in pd-faust this is actually the default, which can be disabled with the `no-slider-nums` option.

• **exclude=pat,...**: Exclude the controls whose labels match the given glob patterns from the Pd GUI.

In pd-faust there is no way to specify the above options on the command line, so you’ll have to put them as `pd` attributes on the `main` group of your Faust program, as described in the faust2pd documentation. For instance:

```faust
process = vgroup("[pd:no-slider-nums][pd:font-size=12]", ...);
```

In addition, the following options can be used to change the appearance of individual control items. If present, these options override the corresponding defaults. Each option can also be prefixed with “no-” to negate the option value. (Thus, e.g., `no-hidden` makes items visible which would otherwise, by means of the global `exclude` option, be removed from the GUI.)

• **hidden**: Hides the corresponding control in the Pd GUI. This is the only option which can also be used for group controls, in which case all controls in the group will become invisible in the Pd GUI.

• **fake-button, radio-slider, slider-num**: These have the same meaning as the corresponding global options, but apply to individual control items.

Again, these options are specified with the `pd` attribute in the label of the corresponding Faust control. For instance, the following Faust code hides the controls in the `aux` group, removes the number entry from the `pan` control, and renders the `preset` item as a Pd radio control:

```faust
aux = vgroup("aux [pd:hidden]", aux_part);
pan = hslider("pan [pd:no-slider-num]", 0, -1, 1, 0.01);
preset = nentry("preset [pd:radio-slider]", 0, 0, 7, 1);
```

### 32.3.10 Remote Control

Also included in the sources is a helper abstraction `faust-remote.pd` and an accompanying elisp package `faust-remote.el`. These work pretty much like pure-remote.pd and pure-remote.el in the `pd-pure` distribution, but are tailored for the remote control of Faust dsps in a Pd patch. In particular, they enable you to quickly compile Faust sources (C-C C-K command) and reload the compiled dsps in Pd (C-C C-X) from Emacs. Clicking the bang control in the faust-remote.pd abstraction also reloads all Faust dsps.

The `faust-remote.el` package was designed to be used with Juan Romero’s Emacs Faust mode; please see `etc/faust-remote.el` in the pd-faust source for usage instructions. Note that at present `faust-remote.el` isn’t installed automatically. You can do this manually by just copying the file to your Emacs site-lisp directory or any other location on the Emacs load-path. E.g., on Linux and other Unix-like systems:

```
sudo cp etc/faust-remote.el /usr/share/emacs/site-lisp/
```

To enable the package, put the following line into your `.emacs` configuration file (this also auto-loads Faust mode):

```
32.3.10 Remote Control 797
```
32.4 Caveats and Bugs

Some parts of this software might still be experimental, under construction and/or bug-ridden. Bug reports, patches and suggestions are welcome.

In particular, please note the following known limitations in the current implementation:

- The names of the voice controls of instrument units (freq, gain, gate) are currently hard-coded, as are the names of the midi, osc and dsp subfolders used to locate various kinds of files.

- Only control change, note and pitch bend messages are supported in the MIDI interface right now, so you’ll have to use, e.g., control changes as a replacement for unsupported types of messages such as key and channel pressure if needed. (You might also consider using the author’s midizap program to do any required remapping.) Coarse/fine pairs of MIDI controllers aren’t directly supported either, so you’ll have to implement these yourself as two separate Faust controls.

- There’s no translation of OSC values. pd-faust thus always assumes that the controls of an external OSC device have the ranges specified in the Faust program. If this isn’t the case then you’ll have to adjust either the OSC controller setup or the control ranges in the Faust program, or use an external tool like OSCulator to translate the messages.

Also, please check the TODO file included in the distribution for other issues which we are already aware of and which will hopefully be addressed in future pd-faust versions.
Chapter 33

pd-pure: Pd loader for Pure scripts

Version 0.26, October 05, 2018

Albert Graef <aggrae@gmail.com>

This is a Pure “loader plugin” for Pd, Miller Puckette’s graphical dataflow programming system for realtime multimedia applications. If you are a Pd user, it lets you write external Pd objects in Pure, which is generally much more convenient and a lot more fun than having to code Pd externals in a comparatively low-level language such as C or C++. If you are a Pure user, it provides you with an alternative way to develop and run your Pure scripts in one of the best graphical dataflow environments available today.

Pure certainly has its own learning curve, but once mastered, it makes programming many kinds of Pd objects a walk in the park. Its Pd interface is convenient to use and has live-coding support, i.e., the ability to reload Pure externals at any time while your Pd patch keeps running. Pure also offers a comprehensive library and many interfaces to third-party software useful for implementing Pd objects, such as Octave and Grame’s Faust.

But pd-pure isn’t limited to just computer music and realtime multimedia programming, which are Pd’s hallmark applications. It also allows you to employ Pd as a graphical dataflow environment for developing and testing your Pure programs, leveraging Pd’s built-in facilities for creating graphical user interfaces for your application, while getting Pd’s sophisticated realtime multimedia capabilities for free.

Note: Pure is a JIT (“just in time”) compiled language which means that there may be some noticeable latencies when the embedded Pure runtime first loads your Pure scripts and compiles them on the fly. This shouldn’t be much of an issue on most contemporary hardware any more, and once the scripts have been loaded, they are executed very efficiently. Nevertheless, as a remedy it is also possible to precompile a collection of Pure objects to a binary external library which can be loaded quickly at startup with Pd’s -lib option. In addition, pd-pure 0.24+ offers the ability to preload Pure source scripts with the -lib option at startup, so that they don’t cause any more hiccups when the objects are instantiated later.
### 33.1 Copying

Copyright (c) 2009-2018 by Albert Graef. pd-pure is distributed under a 3-clause BSD-style license, please see the included COPYING file for details.

### 33.2 Installation

You’ll need Pure 0.50+ and Pd 0.43+. We recommend using Pd versions 0.47.0 and above, since these offer substantial improvements in Pd’s “loader” functionality which pd-pure hooks into to provide Pure object creation.

Usually, make && sudo make install should do the trick. This will compile the external (you need to have GNU make, Pd and Pure installed to do that) and install it in the lib/pd/extra/pure directory.

The Makefile tries to guess the installation prefix under which Pd is installed. If it guesses wrong, you can tell it the right prefix with make prefix=/some/path. Or you can specify the exact path of the lib/pd directory with make pdlibdir=/some/path; by default the Makefile assumes $(prefix)/lib/pd.

It is also possible to specify an alternative flavor of Pd when building and installing the module, by adding a definition like PD=std-extended to the make command line. This is known to work with pd-extended and pd-l2ork, two popular alternative Pd distributions available on the web, as well as pd-l2ork’s latest cross-platform version purr-data. (If you’re going with one of these, we recommend using purr-data since it has all the latest loader improvements.)

The Makefile also tries to guess the host system type and Pure version, and set up some platform-specific things accordingly. If this doesn’t work for your system then you’ll have to edit the Makefile accordingly.

MS Windows users please note that there’s a binary package available at the Pure website, please check the Pure on Windows wiki page for details. In addition, you will also need an installation of the Pure interpreter itself; a corresponding Windows installer can be found in the download section of the Pure website as well (look for the latest pure msi package).

Mac users can find pd-pure and all its dependencies in MacPorts. Please also check the Pure on Mac OS X wiki page for details.

### 33.3 Usage

After installation, you still have to tell Pd to load the Pure external at startup, either with the -lib option (pd -lib pure), or by specifying pure in Pd’s startup options. This setting can be saved so that the Pure loader is always available when you run Pd. Once the Pure loader has been activated, you should see a sign-on message like the following in the Pd main window, indicating that the external has been successfully loaded:
Since version 0.12 pd-pure supports the definition of both control and signal objects in Pure. The latter are also known as “tilde” or “dsp objects” in Pd parlance; pd-pure follows the Pd convention in that these objects have a trailing tilde in their name. Signal objects are used primarily for processing audio signals, whereas control objects are employed for asynchronous message processing.

Simple “one-off” control objects can be created with the \[pure\] class which takes the function to be evaluated as its argument. For instance:

\[pure (+5)\]

This object takes numbers as inputs on its single inlet, adds 5 to them and outputs the result on its single outlet.

Similarly, signal objects can be created with \[pure~\]. For instance, the following object processes incoming vectors of samples, multiplying each sample with 2:

\[pure~ map (*2)\]

Note that in this case the object has actually two inlet/outlet pairs. The leftmost inlet/outlet pair is reserved for the processing of control messages (not used in this example), while the actual signal input and output can be found on the right.

(Pure objects can also be configured to adjust the number of inlets and outlets. This will be described later.)

The argument of \[pure\] and \[pure~\] can be any Pure expression (including local functions and variables, conditionals, etc.). We also refer to these as anonymous Pure objects. If an object is quite complicated or used several times in a patch, it is more convenient to implement it as a named object instead. To these ends, the object function is stored in a corresponding Pure script named after the object. For instance, we might put the following add function into a script named add.pure:

\[
add x y = x+y;
\]

Now we can use the following object in a Pd patch:

\[add 5\]

The Pure loader then recognizes add as an instance of the object implemented by the add.pure file and loads the script into the Pure interpreter. The creation parameter 5 is passed as the first argument of the add function in this example, while the \textit{y} argument comes from the object’s inlet. The function performed by this object is thus the same as with \[pure (+5)\] above.

More examples can be found in the pure-help.pd and pure~help.pd patches. These can also be accessed in Pd by right-clicking on any Pure object and selecting the \texttt{Help} option. (Recent pd-pure versions also allow you to right-click and select \texttt{Open} to open the script of a named
Pure object in a text editor, provided that your Pd version supports the menu-open command. Most reasonably recent Pd versions and flavors do.)

In the following section, we first discuss in detail how control objects are defined and used. After that, the necessary adjustments for implementing signal objects are explained. Some advanced uses of pd-pure are described under Advanced Features.

### 33.4 Control Objects

Basically, to implement a Pd control object named `foo`, all you have to do is supply a Pure script named `foo.pure` which defines a function `foo` (and anything else that you might need to define the function). This function is also called the object function. You can put the script containing the object function either in the same directory as the Pd patch in which you want to use the `foo` object, or anywhere on Pd’s search path. (The latter is useful if the object is to be used in several patches located in different subdirectories. Also note that the former requires that you already saved the Pd patch in the directory containing the `foo.pure` script before you create a `foo` object in it, so that the Pure loader finds the script.)

The script will be executed once, at the time the first object with the given name is created, and will be executed in the directory where it is located. Thus, if the script needs to import other Pure scripts or load some data files, you can put these into the same directory so that the object script can find them.

The `foo` function gets evaluated at object creation time, receiving any additional parameters the object is created with. The resulting Pure expression should be another function which is executed at runtime, passing Pd messages from the inlets as parameters, and routing the function results to the outlets of the object. This two-stage definition process is useful because it allows special processing (such as initialization of required data structures) to be done at object creation time. However, the result of evaluating `foo` can also just be `foo` itself if no such special processing is needed. If we need to distinguish these two stages, we also call the two functions the creation and the runtime function of the object, respectively.

Pd messages are translated to corresponding Pure expressions and vice versa in a straightforward fashion. Special support is provided for converting between the natural Pd and Pure representations of floating point numbers, symbols and lists. The following table summarizes the available conversions.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Pd</th>
<th>Pure</th>
</tr>
</thead>
<tbody>
<tr>
<td>symbol</td>
<td><code>foo</code></td>
<td><code>foo</code></td>
</tr>
<tr>
<td>string</td>
<td><code>a&amp;b</code></td>
<td>&quot;a&amp;b&quot;</td>
</tr>
<tr>
<td>float</td>
<td><code>float 1.23</code></td>
<td><code>1.23</code></td>
</tr>
<tr>
<td>list</td>
<td><code>list 1 2 3</code></td>
<td><code>[1.0,2.0,3.0]</code></td>
</tr>
<tr>
<td>other</td>
<td><code>foo a 2 3</code></td>
<td><code>foo a 2.0 3.0</code></td>
</tr>
</tbody>
</table>

Note that Pd symbols which are no valid Pure symbols become strings in Pure. Conversely, both symbols and strings in Pure are mapped to corresponding Pd symbols. Pure (machine) integers and floating point values both become `float` messages in Pd. Pd list messages are translated to Pure list values, while other aggregate messages are mapped to Pure applications (and vice versa).
33.4.1 Simple Objects

By default, a Pure object has just one inlet and one outlet and thus acts like a simple function with no internal state. For instance, the following object accepts Pd float messages and adds 5 to each received value:

```
add5 x = x+5;
```

In the Pd patch each [add5] object then has a single inlet supplying parameters and a single outlet for results of the add5 function.

33.4.2 Creation Arguments

You can parameterize an object with creation arguments, which are passed to the Pure function at object creation time. For instance:

```
add x y = x+y;
```

This object can then be invoked, e.g., as [add 5] in the Pd patch to supply the needed creation argument x. Please note that only a fixed number of creation arguments can be processed this way. However, the Pure loader also provides a mechanism to handle a variable number of creation arguments, see Variadic Creation Functions below.

33.4.3 The [pure] Object

For simple kinds of objects like the above, the Pure loader provides the generic [pure] object as a quick means to create Pure control objects without actually preparing a script file. The creation parameter of [pure] is the object function. This can be a predefined Pure function, or you can define it on the fly in a with clause. You can also just load additional script files defining the functions you use with [pure]; see Controlling the Runtime and Loading Script Files at Startup for details.

For instance, [pure succ] uses the predefined Pure function succ which adds 1 to its input, while the object [pure add 5 with add x y = x+y end] produces the same results as the [add 5] object defined using a separate add.pure script in the previous section. You can also generate constant values that way. E.g., the object [pure cst 1.618] responds to any message (such as bang) by producing the constant value 1.618, while the object [pure cst (1..10)] yields the constant list containing the numbers 1..10.

33.4.4 Multiple Output Messages

A Pure object can also output multiple messages in one go, by enclosing the sequence of messages to be output in curly brance (which turns them into a Pure vector). The messages will be output in the indicated order. E.g., the following [dup] object sends out each received message twice:

```
dup x = {x,x};
```

Note that this is different from the following, which outputs a list value to the outlet instead:
dup2 x = [x,x];

An object can also just “swallow” messages and generate no output at all. To these ends, an object may return either an empty vector \( \{ \} \) or the empty tuple \( () \). (Note that, in contrast, returning the empty list \( [] \) does send a value back to Pd, namely an empty list value.) For instance, the following object \([\text{echo}]\) implements a sink which just prints received messages on standard output, which is useful for debugging purposes:

```plaintext
using system;
echo x = () when puts (str x) end;
```

Using the facilities for configuring the inlets and outlets of an object described in the next section, you could also implement this object as follows, by just removing the superfluous outlet (in this case all return values from the function will be ignored anyway):

```plaintext
using system;
echo = 1,0,puts.str;
```

### 33.4.5 Configuring Inlets and Outlets

To create an object with multiple inlets and outlets for control messages, the object creation function must return the desired numbers of inlets and outlets, along with a second function to be applied at runtime, as a tuple \( n,m,\text{foo} \). The input arguments to the runtime function as well as the corresponding function results are then encoded as pairs \( k,\text{val} \) where \( k \) denotes the inlet or outlet index. (Note that the \( k \) index is provided only if there actually is more than one inlet. Also, the outlet index is assumed to be zero if none is specified, so that it can be omitted if there’s only one outlet.)

For instance, the following object, invoked as \([\text{cross}]\) in the Pd patch, has two inlets and two outlets and routes messages from the left inlet to the right outlet and vice versa:

```plaintext
cross = 2,2,cross with cross (k,x) = (1-k,x) end;
```

You can also emit multiple messages to different outlets in one go. These are encoded as vectors of \( \text{index, value} \) pairs which are emitted in the order in which they are written. E.g., the following \([\text{fan}]\) object implements an “\( n \)-fan” which routes its input to \( n \) outlets simultaneously:

```plaintext
fan n = 1,n,fan with fan x = reverse {k,x | k = 0..n-1} end;
```

Note that, because of the use of \text{reverse}, the \( n \) outlets are served in right-to-left order here. This is not strictly necessary, but matches the Pd convention.

An object can even change its number of inlets and outlets dynamically at runtime, using the \text{pd_configure()}\ function described in the Programming Interface section. E.g., the following object accepts lists of two numbers and changes its number of inlets and outlets accordingly:
using pd;
inout [n,m] |
inout (0,[n,m]) = pd_configure (int n) (int m);

33.4.6 Variadic Creation Functions

Sometimes you may wish to implement an object which accepts a variable number of creation arguments. To these ends, the creation function foo may return an application of the form varargs bar. In this case, the function bar becomes the actual object creation function which is applied to a single argument, the list of all supplied creation arguments. For instance, if you invoke foo through an object like [foo a b c] in a patch, the loader would then create the object by calling bar [a,b,c] instead. Likewise, if the object gets created without any arguments at all, i.e., [foo], then bar would be called as bar[]. The function bar may then be used as the runtime function of the object, or it may yield the object function to be used, along with the desired number of inlets and outlets, as described in the previous subsection. This makes it possible to configure the inlets and outlets of the object according to the number and values of the supplied creation arguments, pretty much like some of the built-in Pd objects do, such as pack and sel.

For instance, here is how you could implement something like Pd’s built-in sel object in Pure. The object compares its input against a number of values given as creation arguments, and bangs the corresponding outlet if it is found, or passes on the input on the rightmost outlet otherwise:

mysel = varargs mysel with
    mysel xs = 1,#xs+1,mysel with
        mysel x = i,bang if i<#xs when i = #takewhile (~==x) xs end;
        #xs,x otherwise;
    end;
end;

end

Note that the runtime function is the innermost local mysel function (at line 3 in the example). The outermost local mysel function (at line 2) is the actual creation function which gets invoked by the loader on the list of all creation arguments; here it yields the number of inlets and outlets (where the latter depends on the number of creation arguments) along with the runtime function. You can invoke this object as, e.g., [mysel a b c], in which case there will be four outlets, one for each given value and one for the rightmost “default” outlet.

33.4.7 Local State

Local state can be kept in Pure reference values. For instance, the following [mycounter] object produces the next counter value when receiving a bang message:

nonfix bang;
mycounter = next (ref 0) with
    next r bang = put r (get r+1);
    next _ _ = () otherwise;
end;

33.4.6 Variadic Creation Functions
Note that the state is kept as an additional first parameter to the local function `next` here. Alternatively, you can also make the state a local variable of `mycounter`:

```pure
nonfix bang;
mycounter = next with
next bang = put r (get r+1);
next _ = () otherwise;
end when r = ref 0 end;
```

### 33.5 Signal Objects

If the name of a Pure object (i.e., the basename of the corresponding Pure script) ends with the `~` character, pd-pure assumes that it denotes a signal object whose primary purpose is to process sample data. The basic setup is similar to the case of control objects, with the following differences:

- The object function for a signal object `xyz~` is named `xyz_dsp` (rather than `xyz`). The function is defined in the `xyz~.pure` script file, which must be located in the same directory as the Pd patch or anywhere on Pd’s search path.

- To keep things simple, a Pure signal object is always equipped with exactly one control inlet and one control outlet, which are the leftmost inlet and outlet of the object. These can be used to process control messages in the usual fashion, in addition to the audio processing performed by the object.

- Any additional inlets and outlets of the object are signal inlets and outlets. By default, one signal inlet/outlet pair will be provided. Configuring a custom number of signal inlets and outlets works as with control objects. In this case the object creation function must return a triple `n,m,foo` where `n` and `m` are the desired number of signal inlets and outlets, respectively, and `foo` is the actual processing function to be invoked at runtime.

**Note:** pd-pure’s convention of placing the control inlet/outlet pair of a signal object on the left is somewhat at odds with most other signal objects in Pd, which typically have a (main) signal inlet/outlet on the left and the control inlets and outlets on the right. However, we think that this kind of setup makes the most sense for Pure signal objects, since the control inlet/outlet pair will always be there in the same position, whereas the signal inlets and outlets may vary (and might actually not be present at all, e.g., if the sole purpose of a signal object is to have some code executed for each “dsp tick”).

Whenever Pd has audio processing enabled, the object function is invoked with one block of sample data for each iteration of Pd’s audio loop. The sample data is encoded as a double matrix which has one row for each signal inlet of the object; row 0 holds the sample data for the first signal inlet, row 1 the sample data for the second signal inlet, etc. The row size corresponds to Pd’s `block size` which indicates how many samples per signal connection is processed in one go for each iteration of the audio loop. (Usually the default block size is 64, but this can be changed with Pd’s `-blocksize` option and also on a per-window basis using the `block~` object, see the Pd documentation for details.) Note that the input matrix will
have zero rows if the object has zero signal inlets, in which case the row size of the matrix (as reported by the `dim` function) still indicates the block size.

When invoked with a signal matrix as argument, the object function should return another double matrix with the resulting sample data for the signal outlets of the object, which normally has one row per outlet and the same row size as the input matrix. (A lack or surplus of samples in the output matrix is handled gracefully, however. Missing samples are filled with zeros, while extra samples are silently ignored.)

For instance, here’s a simple object with the default single signal inlet/outlet pair (in addition to the leftmost control inlet/outlet pair, which isn’t used in this example). This object just multiplies its input signal by 2:

```
mul2_dsp x::matrix = map (*2) x;
```

This code would then be placed into a script file named `mul2~.dsp` and invoked in Pd as an object of the form `[mul2~].

As with control objects, there’s a shortcut to create simple objects like these without preparing a script file, using the built-in `[pure~]` object. Thus the `dsp` function in the previous example could also be implemented using an object of the form `[pure~ map (*2)]` (which uses the same function, albeit in curried form).

Creation parameters can also be used in the same way as with control objects. The following object is to be invoked in Pd as `[mul~ f]` where `f` is the desired gain factor.

```
mul_dsp f::double x::matrix = map (*f) x;
```

Next, let’s try a custom number of signal inlets and outlets. The following object has two signal inlets and one signal outlet. Like Pd’s built-in `[*~]` object, it multiplies the two input signals, producing an amplitude (or ring) modulation effect:

```
sigmul_dsp = 2,1,sigmul
  sigmul x::matrix = zipwith (*) (row x 0) (row x 1);
end;
```

Here’s another example which takes no inputs and produces one output signal, a random wave (i.e., white noise). Note the use of the `dim` function to determine the number of samples to be generated for each block.

```
extern double genrand_reall() = random1;
randomwave1_dsp = 0,1,randomwave
  randomwave in::matrix = {random | i=1..n} when _,n = dim in end;
  random = random1+2-1;
end;
```

Control messages for the control outlet of the object may be added by returning a pair `sig,msg` where `sig` is the output signal matrix and `msg` is a single control message or vector of such messages (using the same format as with control objects). The signal matrix can also be omitted if no signal output is needed (unless the control data takes the form of a double matrix, which would be interpreted as signal data; in such a case you’d have to specify an empty signal matrix instead). The object function may also return `()` if neither signal
nor control output is required. (This may be the case, e.g., for dpss which just analyze the incoming signal data and store the results somewhere for later retrieval.)

Signal objects can also process control messages and generate responses on the leftmost inlet/outlet pair as usual. This is commonly used to set and retrieve various control parameters used or generated by the audio processing part of the object.

For instance, here is a signal object which plays back a soundfile using the sndfile module (cf. pure-audio). The object function reads the entire file (whose name is passed as a creation argument) at creation time and turns over processing to the playsf function which returns one block of samples from the file (along with the current position of the playback pointer) for each invocation with an (empty) input matrix. In addition, a bang message is output when the end of the file is reached. The object also responds to floating point values in the range from 0 to 1 on the control inlet by adjusting the playback pointer accordingly.

```
using sndfile;

nonfix bang;

playsf_dsp name = 0,nchannels,playsf with
// Play one block of samples. Also output a number in the range 0..1 on the
// control outlet to indicate the current position.
playsf x::matrix = block,get pos/nsamples when
      _,n = dim x; block = submat buf (0,get pos) (nchannels,n);
      put pos (get pos+n);
end if get pos>=0 && get pos<=nsamples;
// Output a bang once to indicate that we’re done.
playsf x::matrix = bang when
      _,n = dim x; put pos (-1);
end if get pos>=0;
playsf _::matrix = ();
// A number in the range 0..1 places the playback pointer accordingly.
playsf x::double = put pos $ int $ round $ x*nsamples $$ ()
end when

// Open the audio file for reading.
info = sf_info (); sf = sf_open name SFM_READ info;
// Get some information about the file.
nsamples,rate,nchannels,_ = sf_get_info info;
nchannels = int nsamples;
// Read the file into memory.
buf = dmatrix (nsamples,nchannels);
nsamples = int $ sf_readf_double sf buf nsamples;
// Convert interleaved samples (nsamples x nchannels) to one channel per row
// (nchannels x nsamples).
buf = transpose buf;
// Initialize the playback pointer:
pos = ref 0;
end;
```

As another example, here’s a complete stereo amplifier stage with bass, treble, gain and balance controls and a dB meter. The dsp part is implemented in Faust, Grame’s functional dsp programming language. The Pure program just does the necessary interfacing to Pd,
which includes processing of incoming control messages for setting the control parameters of the Faust dsp, and the generation of output control messages to send the dB meter values (also computed in the Faust dsp) to Pd. (To run this example, you need the “faust2” branch of the Faust compiler so that the dsp can be inlined into the Pure program. Note that the entire section inside the `<%>` braces is Faust code.)

```plaintext
%< -*- dsp:amp -*-

import("math.lib");
import("music.lib");

/* Fixed bass and treble frequencies. You might want to tune these for your setup. */
bass_freq        = 300;
treble_freq      = 1200;

/* Bass and treble gain controls in dB. The range of +/-20 corresponds to a boost/cut factor of 10. */
bass_gain        = nentry("bass", 0, -20, 20, 0.1);
treble_gain      = nentry("treble", 0, -20, 20, 0.1);

/* Gain and balance controls. */
gain             = db2linear(nentry("gain", 0, -96, 96, 0.1));
bal              = hslider("balance", 0, -1, 1, 0.001);

/* Balance a stereo signal by attenuating the left channel if balance is on the right and vice versa. I found that a linear control works best here. */
balance          = *(1-max(0,bal)), *(1-max(0,0-bal));

/* Generic biquad filter. */
filter(b0,b1,b2,a0,a1,a2) = f | (+ ~ g)
with {
    f(x) = (b0/a0)*x+(b1/a0)*x'+(b2/a0)*x'';
    g(y) = 0-(a1/a0)*y-(a2/a0)*y';
}

/* Low and high shelf filters, straight from Robert Bristow-Johnson’s “Audio EQ Cookbook”, see http://www.musicdsp.org/files/Audio-EQ-Cookbook.txt. f0 is the shelf midpoint frequency, g the desired gain in dB. S is the shelf slope parameter, we always set that to 1 here. */
low_shelf(f0,g) = filter(b0,b1,b2,a0,a1,a2)
with {
    S = 1;
    A = pow(10,g/40);
    w0 = 2*PI*f0/SR;
    alpha = sin(w0)/2 * sqrt( (A + 1/A)*(1/S - 1) + 2 );
}
```

33.5 Signal Objects 809
b0 = A*( (A+1) - (A-1)*cos(w0) + 2*sqrt(A)*alpha );
b1 = 2*A*( (A-1) - (A+1)*cos(w0) );
b2 = A*( (A+1) - (A-1)*cos(w0) - 2*sqrt(A)*alpha );
a0 = (A+1) + (A-1)*cos(w0) + 2*sqrt(A)*alpha;
a1 = -2*( (A-1) + (A+1)*cos(w0) );
a2 = (A+1) + (A-1)*cos(w0) - 2*sqrt(A)*alpha;
}

high_shelf(f0,g) = filter(b0,b1,b2,a0,a1,a2)
with {
    S = 1;
    A = pow(10,g/40);
    w0 = 2*PI*f0/SR;
    alpha = sin(w0)/2 * sqrt( (A + 1/A)*(1/S - 1) + 2 );

    b0 = A*( (A+1) + (A-1)*cos(w0) + 2*sqrt(A)*alpha );
    b1 = -2*A*( (A-1) + (A+1)*cos(w0) );
    b2 = A*( (A+1) + (A-1)*cos(w0) - 2*sqrt(A)*alpha );
    a0 = (A+1) - (A-1)*cos(w0) + 2*sqrt(A)*alpha;
    a1 = 2*( (A-1) - (A+1)*cos(w0) );
    a2 = (A+1) - (A-1)*cos(w0) - 2*sqrt(A)*alpha;
}

/* The tone control. We simply run a low and a high shelf in series here. */
tone = low_shelf(bass_freq,bass_gain)
     : high_shelf(treble_freq,treble_gain);

/* Envelop follower. This is basically a 1 pole LP with configurable attack/release time. The result is converted to dB. You have to set the desired attack/release time in seconds using the t parameter below. */
t = 0.1; // attack/release time in seconds
g = exp(-1/(SR*t)); // corresponding gain factor

env = abs : *(1-g) : + - *(g) : linear2db;

/* Use this if you want the RMS instead. Note that this doesn't really calculate an RMS value (you'd need an FIR for that), but in practice our simple 1 pole IIR filter works just as well. */
rms = sqr : *(1-g) : + - *(g) : sqrt : linear2db;
sqr(x) = x*x;

/* The dB meters for left and right channel. These are passive controls. */
left_meter(x) = attach(x, env(x) : hbargraph("left", -96, 10));
right_meter(x) = attach(x, env(x) : hbargraph("right", -96, 10));

/* The main program of the Faust dsp. */
process = (tone, tone) : (_*gain, _*gain) : balance
Pure Language and Library Documentation, Release 0.68

: (left_meter, right_meter);

// These are provided by the Pd runtime.
extern float sys_getsr(), int sys_getblksize();
// Provide some reasonable default values in case the above are missing.
sys_getsr = 48000; sys_getblksize = 64;

// Get Pd’s default sample rate and block size.
const SR = int sys_getsr;
const n = sys_getblksize;

using faustui;

amp dsp = k,l,amp with
// The dsp part. This also outputs the left and right dbmeter values for
// each processed block of samples on the control outlet, using messages of
// the form left <value> and right <value>, respectively.
amp in::matrix = amp::compute dsp n in out $$
    out,(left (get_control left_meter),right (get_control right_meter));
// Respond to control messages of the form <control> <value>. <control> may
// be any of the input controls supported by the Faust program (bass,
// treble, gain, etc.).
amp (@@ x::double) = put_control (ui!str c) x $$ x;
end when
// Initialize the dsp.
dsp = amp::newinit SR;
// Get the number of inputs and outputs and the control variables.
k,l,ui = amp::info dsp;
ui = control_map $ controls ui;
{left_meter,right_meter} = ui!!["left","right"]; // Create a buffer large enough to hold the output from the dsp.
out = dmatrix (l,n);
end;

Note that it is possible to load the above Faust program directly in Pd, using the facilities described in faust2pd: Pd Patch Generator for Faust. This is also more efficient since it avoids the overhead of the extra Pure layer. However, invoking Faust dsp’s via Pure also offers some benefits. In particular, it enables you to add more sophisticated control processing, interface to other 3rd party software for additional pre- and postprocessing of the signal data, or do live editing of Faust programs using the facilities described in Livecoding below. An actual Pure implementation of a Faust external which does all this and provides the extra conveniences of faust2pd under one hood can be found in pd-faust.

33.6 Advanced Features

This section discusses some advanced features of the Pd Pure loader. It explains the use of timer callbacks, “wireless” connections (send/receive), wave arrays, and the runtime control and livecoding facilities. We also give an overview of the API provided for pd-pure programmers.
33.6.1 Asynchronous Messages

pd-pure provides a simple asynchronous messaging facility which allows a Pure object to schedule a message to be delivered to itself later. This is useful for implementing all kinds of delays and, more generally, any kind of object which, once triggered, does its own sequencing of control messages.

To these ends, the object function may return a special message of the form \( \text{pd\_delay}\ t\ \text{msg} \) (either by itself or as an element of a result list) to indicate that the message \( \text{msg} \) should be delivered to the object function after \( t \) milliseconds (where \( t \) is either a machine int or a double value). After the prescribed delay the object function will then be invoked on the given message, and the results of this call are processed as usual (routing messages to outlets and/or scheduling new timer events in response to further pd\_delay messages). Note that if the delay is zero or negative, the message is scheduled to be delivered immediately.

For instance, a simple kind of delay object can be implemented in Pure as follows:

```pure
mydelay _ (alarm msg) = msg;
mydelay t msg = pd_delay t (alarm msg) otherwise;
```

The desired delay time is specified as a creation argument. The first equation handles messages of the form \( \text{alarm}\ \text{msg} \); the action is to just output the delayed message given by the \( \text{msg} \) argument. All other input messages are scheduled by the second equation, which wraps the message in an \( \text{alarm} \) term so that it gets processed by the first equation when it is delivered.

Note that pd-pure only allows you to schedule a single asynchronous event per call of the object function. Thus, if the mydelay object above receives another message while it is still waiting for the previous one to be delivered, the old timer is cancelled and the new one is scheduled instead; this works like Pd’s builtin \text{delay} object.

Moreover, scheduling a new event at an infinite (or \text{nan}) time value cancels any existing timer. (Note that you still have to specify the \text{msg} parameter, but it will be ignored in this case.) We can use this to equip our mydelay object with a stop message as follows:

```pure
nonfix stop;
mydelay _ (alarm msg) = msg;
mydelay _ stop = pd_delay inf ();
mydelay t msg = pd_delay t (alarm msg) otherwise;
```

More elaborate functionality can be built on top of the basic timer facility. The following example shows how to maintain a timed message queue in a Pure list, in order to implement a simple delay line similar to Pd’s builtin \text{pipe} object. Here we also employ the \text{pd\_time()} function, which is provided by the Pure loader so that Pure scripts can access the current logical Pd time in milliseconds (see Programming Interface below). This is convenient if we need to deal with absolute time values, which we use in this example to keep track of the times at which messages in the queue are to be delivered:

```pure
extern double \text{pd\_time());
mypipe t = process (ref []) with
  process q () = case dequeue q of
```
x, (t,..):_ = {x, pd_delay (t - pd_time) ()};
x, _ = x;
end;

process q x = enqueue q x $$ pd_delay t () if null (get q);
= enqueue q x $$ () otherwise;
enqueue q x = put q $ get q + [(pd_time + t, x)];
dequeue q = x, put q xs when (_, x):xs = get q end;
end;

33.6.2 Wireless Messaging

As of version 0.14, pd-pure offers some facilities for sending and receiving messages directly, without any wired connections to the inlets and outlets of an object (similar to what the Pd [send] and [receive] objects provide). See the description for the pd_send() and pd_receive() routines in the Programming Interface section.

For instance, here’s how you can use the pd_send function to send messages to the Pd run-time:

```
pd_send "pd" (dsp 1); // turn on audio processing
```

This function also enables you to perform dynamic patching, by sending the appropriate messages to patches (i.e., "pd-patch" receivers, where patch is the name of the target patch). Useful messages to patches are listed in the Tips and Tricks section on the Pd community website, and some examples can be found here. For instance, the following Pure object, when banged, inserts a few objects into a subpatch named test and connects them to each other:

```
extern void pd_send(char*, expr*);

pd_send_test = () when
    pd_send "pd-test" (obj 10 0 "osc~" 220);
pd_send "pd-test" (obj 10 30 "*~" 0.1);
pd_send "pd-test" (obj 10 60 "dac-");
pd_send "pd-test" (connect 0 0 1 0);
pd_send "pd-test" (connect 1 0 2 0);
pd_send "pd-test" (connect 1 0 2 1);
end;
```

An object can also receive messages from any named source by means of the pd_receive function. This function must be called either at object creation time or when one of the dsp or control processing methods of the object is invoked. For instance, the following object calls pd_receive at creation time in order to receive messages sent to the left and right receivers, and outputs them on its left or right outlet, respectively:

```
extern void pd_receive(char*);

pd_receive_test = 1,2,process with
    process (left x) = 0,x;
    process (right x) = 1,x;
end when
```
Please note that `pd_receive` itself doesn’t return any message, it merely registers a receiver symbol so that messages sent to that symbol may be received later. The received messages are always delivered to the leftmost inlet when Pd does its control processing. Moreover, the symbol identifying the source of the message is applied to the message itself, so that the receiver can figure out where the message came from and adjust accordingly. This operation is useful, in particular, to provide communication channels between Pd GUI elements and Pure objects. Wireless connections are often preferred in such cases, to reduce display clutter.

33.6.3 Reading and Writing Audio Data

Besides the realtime processing of audio data, Pd also provides a means to store sample data in *arrays* which can be displayed in a patch and modified interactively, see the section on numeric arrays in the Pd documentation for details. Arrays can be used, e.g., as running waveform displays, as wavetables which are played back in the audio loop, or as waveshaping functions used to implement distortion effects.

Each array has a name (Pd symbol) under which it can be accessed from Pure code. pd-pure makes it possible to transfer audio data directly between Pd arrays and Pure double vectors by means of the `pd_getbuffer()` and `pd_setbuffer()` routines. Please see Programming Interface below for a closer description of the provided routines.

For instance, here is a `randomwave` object which fills a Pd array (whose name is given as the creation argument) with random values in response to a `bang` message:

```plaintext
extern double genrand_real1() = random1;
extern int pd_getbuffersize(char *name);
extern void pd_setbuffer(char *name, expr *x);

nonfix bang;

randomwave name = 1,0,process with
  process bang = pd_setbuffer name {random | i = 1..nsamples};
  nsamples = pd_getbuffersize name;
  random = random1*2-1;
end;
```

33.6.4 Controlling the Runtime

pd-pure provides a predefined `[pure-runtime]` object which makes it possible to control the embedded Pure interpreter in some ways. There can be any number of `[pure-runtime]` objects in a patch, which all refer to the same instance of the Pure interpreter.

First and foremost, the `[pure-runtime]` object accepts some control messages which can be used to dynamically reload all loaded scripts, and to implement “remote control” of a patch using the `pdsend` program. This is described in more detail in the Livecoding subsection.
The second use of `[pure-runtime]` is to load additional Pure scripts. To these ends, `[pure-runtime]` can be invoked with the names of scripts to be loaded at object creation time as arguments. The script names should be specified without the `.pure` suffix; it will be added automatically. The scripts will be searched for in the directory of the patch containing the `[pure-runtime]` object and on the Pd path. For instance, to load the scripts `foo.pure` and `bar.pure`, you can add the following object to your patch:

```
[pure-runtime foo bar]
```

This facility can be used, in particular, to load any additional scripts needed for anonymous objects defined with `[pure]` and `[pure-]`. Note that you shouldn’t use this to load named Pure objects, you should let the Pure loader handle these as it also keeps track of the scripts in `livecoding`. Another caveat is that you must ensure that the `[pure-runtime]` object is inserted into the patch before any anonymous objects which depend on the loaded scripts. (Also note that the script loading facility of `[pure-runtime]` is by and large considered a legacy feature now that `[declare ~lib]`, discussed in the next subsection, offers a better way to load additional script files using Pd’s built-in `~lib` mechanism.)

Last but not least, you can also specify `-w` as an argument to `[pure-runtime]` in order to enable warnings in the embedded Pure interpreter. This has the same effect as running `pure -w` on the command line. It causes the interpreter to produce additional warning messages for some dubious (albeit correct) constructs, which may be a useful aid, in particular, for Pure novices. This is a global option; once enabled, it applies to all subsequently loaded Pure scripts until the interpreter is restarted from scratch (see `livecoding`). The `-w` option can also be combined with names of scripts to be loaded, e.g.:

```
[pure-runtime -w foo bar]
```

### 33.6.5 Loading Script Files at Startup

As of version 0.24, `pd-pure` provides an easier and more familiar way to load additional Pure scripts using Pd’s `~lib` mechanism during Pd’s startup or when a patch is loaded. Compared to the rather rudimentary script loading facility provided by the `[pure-runtime]` object, this also offers two chief advantages:

- It works with both named Pure objects and auxiliary library scripts defining functions to be used with the `[pure]` and `[pure-]` objects.
- The Pure loader keeps track of the loaded scripts and allows them to be reloaded at any time using the `livecoding` facility.

Note that at present, this feature requires the latest incarnation of the Pd loader, which means that you should make sure that you’re using Pd 0.47.0 or later, or a compatible Pd flavor such as `purr-data`.

To load some script files at startup, just add the corresponding script names (without the `.pure` suffix) to Pd’s startup libraries, or invoke them from the command line using the `-lib` option, just like you’d do with any other Pd externals and libraries. E.g.:
pd -lib foo -lib bar

Note that these options must come after any options required to launch the Pure loader (see Usage above), otherwise Pd will not recognize the scripts as loadable libraries. You can also specify the relative or absolute path to the scripts if needed, for instance:

```
pd -lib ~/pd-pure-externals/foo -lib ~/pd-pure-externals/bar
```

Or you can use Pd’s -path option (or Pd’s search path configuration dialog) to specify where Pd should go looking for the script files:

```
pd -path ~/pd-pure-externals -lib foo -lib bar
```

Note that no special search path will be needed if you just drop the Pure scripts to be loaded into one of the directories on Pd’s default search path. E.g., on Linux this usually includes the ~/pd-externals folder (~/pd-l2ork-externals when using pd-l2ork or purr-data). The default path will be different depending on the platform and Pd flavor you use, so please check your local Pd documentation for details.

The -lib mechanism also works with Pd’s [declare] object, so that, like the [pure-runtime] object, it can also be used in patches. For instance, you can invoke the foo and bar script files in a patch by inserting the following object (using the same -lib and -path options that you’d use on the command line):

```
[declare -lib foo -lib bar]
```

The scripts will then be loaded automagically as soon as you open the patch in Pd. (Note that, as with the [pure-runtime] object, the [declare] object needs to be inserted before any objects which depend on the loaded scripts.) This facility is most useful with anonymous objects, since named objects will be loaded anyway if needed, if you just type their name into an object box. But it works with named objects, too, and it also allows you to mix and match named and anonymous objects in a single script file, and make sure that the script gets loaded (and reloaded when livecoding) even if the patch doesn’t contain any instance of the named object at all.

### 33.6.6 Livecoding

Livecoding means changing Pure objects on the fly while a patch is running. A simple, but rather limited way to do this is to just edit the boxes containing Pure objects interactively, as you can do with any kind of Pd object. In this case, the changes take effect immediately after you finish editing a box. However, for more elaborate changes, you may have to edit the underlying Pure scripts and notify the Pure interpreter so that it reloads the scripts. The Pure loader provides the special [pure-runtime] object to do this.

Please note that [pure-runtime] is a rather primitive way of doing these things, so pd-pure also provides a more convenient [pure-remote] helper abstraction which takes care of all the gory details and also provides a useful “remote control” feature. We really recommend using that instead of fiddling around with [pure-runtime], but since [pure-remote] is implemented using [pure-runtime], it may be useful to know how all this works at the most
basic level, which is what we explain below. (If you don’t care about the nitty-gritty stuff then you may just skip ahead to the Remote Control section now.)

Sending a bang to the [pure-runtime] object tells the plugin to reload all object scripts and update the Pure objects in your patch accordingly. The object also provides two outlets to deal with the inevitable latencies caused by the compilation process. The right outlet is banged when the compilation starts and the left outlet gets a bang when the compilation is finished, so that a patch using this facility can respond to these events in the appropriate way (e.g., disabling output during compilation).

The reload message works similarly, but while the bang message only reloads the object scripts, reload restarts the Pure interpreter from scratch and reloads everything, including the prelude and imported modules. This will usually take much longer, but is only necessary if you edited imported library modules which won’t be reloaded with the bang message.

While this facility is tremendously useful for interactive development, there are some limitations and corresponding workarounds that you should keep in mind.

First, since the compilation is done in Pd’s main thread, it may lead to undesirable pauses in Pd’s audio and control processing. With the bang message the delays will usually be small, but may still be noticeable. There’s no way around this in the current implementation, but as a remedy you can try to keep the compilation times to a minimum. This can be achieved by putting all code which you don’t plan to edit “live” into library modules which are imported in the object scripts. By these means, the number of definitions in the object scripts themselves can be kept small, resulting in faster compilation.

Second, note that the reloading of object scripts amounts to a “cold restart” of the Pure objects in your patches. If a Pure object keeps some local state, it will be lost. As a remedy, the loader implements a simple protocol which allows Pure objects to record their internal state before a script gets reloaded, and restore it afterwards. To these ends, a Pure object may respond to the following two messages:

- Before reloading, the Pure object will receive the pd_save message. In response, the object should return a Pure expression encoding its internal state in a way which can be serialized (see the description of the blob function in the Pure Library Manual for details). Usually, it is sufficient to just pack up all state data in a tuple, list or some other aggregate and return that as the response to the pd_save message.

- After reloading, the Pure object will receive a pd_restore state message, where state is the previously recorded state, as returned by the object in response to the pd_save message. It should then restore its internal state from the saved data. (The return value of this message invocation is ignored.)

In order to participate in the pd_save/pd_restore protocol, an object must subscribe to it. This is done by setting pd_save as a sentry on the object function (see the description of the sentry function in the Pure Library Manual for details). For instance, here’s the mycounter example from Local State again, with the necessary additions to support the pd_save/pd_restore protocol:

```plaintext
nonfix bang pd_save;
mycounter = sentry pd_save $ next (ref 0) with
```
next r bang = put r (get r+1);
next r pd_save = get r;
next r (pd_restore n) = put r n;
next _ _ = () OTHERWISE;
end;

33.6.7 Remote Control

The distribution also includes an abstraction pure-remote.pd which you can include in your patch to enable live coding, as well as remote control of the patch through the pdsend program. This abstraction is installed directly under Pd’s extra directory so that normally it should be available without any further ado. As already mentioned, [pure-remote] provides a more convenient way to enable live coding in your patches, so you should normally use this abstraction instead of fiddling around with [pure-runtime] itself.

Sending a bang or reload to [pure-remote] causes a reload of the object scripts, as described under Livecoding above. The former can also be triggered directly by clicking the bang control of the abstraction (which also provides visual feedback while a compilation is still in progress). Note that the single inlet of the abstraction actually gets routed to the embedded [pure-runtime] object, and conversely its two outlets receive the output from that object, so that [pure-remote] can also be operated basically in the same way as [pure-runtime] if needed. But usually the abstraction’s bang control should be all that you need to care about.

For added convenience, [pure-remote] also accepts any other message of the form receiver message and will route the given message to the given receiver. In addition it listens on a certain port (4711 by default, but you can change this inside the abstraction if needed) for messages coming in from other applications, typically via the pdsend program. This is intended to provide remote control of the Pure runtime as well as various parameters in patches. For instance, by having pdsend send a bang to port 4711, you can trigger a reload of the Pure objects in your patches. Moreover, by sending a play 0 or play 1 message, one might implement a simple playback control, provided that your patch includes an appropriate receiver (often a GUI object). See the pure-help.pd patch for an example.

To make these features available in emacs, there’s an accompanying elisp program (pure-remote.el) which contains some keybindings for the necessary pdsend invocations, so that you can operate the pure-remote patch with simple keystrokes directly from the text editor. The same bindings are also available in Emacs Pure mode, but need to be enabled before you can use them; please see the pure-remote.el file for details. As shipped, pure-remote.el and Pure mode implement the following commands:

| C-C C-X  | Quick Reload | Sends a bang message to reload object scripts. |
| C-C M-X  | Full Reload  | Sends a reload message to reload everything.  |
| C-C C-M  | Message      | Prompts for a message and sends it to pure-remote. |
| C-C C-S  | Stop         | Sends a play 0 message.                     |
| C-C C-T  | Restart      | Sends a play 0 message followed by play 1.   |
| C-/-     | Dsp On       | Sends a pd dsp 1 (enable audio processing). |
| C-.-     | Dsp Off      | Sends a pd dsp 0 (disable audio processing). |
Of course you can easily add more like these, just have a look at how the keybindings are implemented in pure-remote.el or pure-mode.el and create your own in an analogous fashion. Together with Pure mode, this gives you a nice interactive environment for developing pd-pure applications.

### 33.6.8 Compiling Objects

pd-pure’s built-in livecoding abilities require that objects are run from source code. As already mentioned, this needs some (in some cases, substantial) time at startup when the Pure interpreter is loaded and your Pure scripts are compiled to native code on the fly. This time is wasted if you are finished developing your Pure objects and just want to run them as they are.

Therefore pd-pure also supports compiling a collection of Pure objects to a binary which can be loaded with Pd’s -lib option just like any other external library of Pd objects. This basically involves using the Pure interpreter as a batch compiler to translate the Pure scripts implementing the objects to a shared library. You also have to link in a small amount of C code so that the shared module can be loaded by Pd and registers its Pd object classes with pd-pure. The examples/libexample folder contains a complete example showing how this is done.

Note that even if you load all your pd-pure objects from such libraries, you still need to load the pd-pure module first, since it provides the basic infrastructure required to run any kind of pd-pure object (no matter whether it’s implemented in compiled or source form).

Also note that, even though compiled objects have no associated script file which can be reloaded on the fly, they can still recreate themselves with the `pd_reload()` routine, see Programming Interface below. This makes it possible for compiled objects to adjust themselves to global state changes in a livecoding situation. However, it’s completely up to a compiled object whether it actually uses that feature and/or responds to the livecoding messages in some way; the built-in livecoding infrastructure by itself only manages source objects.

### 33.6.9 Programming Interface

The Pure loader provides a number of interface routines which can be called by Pure scripts running in the Pd environment. We give a brief description of these functions below. These functions are all implemented in C, so in order to access them in your Pure scripts, you will need corresponding extern declarations (see the “C Interface” section in The Pure Manual for details). For your convenience, there’s a `pd.pure` script included in the distribution which already contains all the required extern declarations, so you just need to import this script in your Pure scripts and you’re set.

The `pd.pure` script will be installed in the lib subfolder along with the Pd Pure loader external and the examples. The embedded Pure runtime has been set up so that it always has this directory in its search path, so that it’s enough to include a declaration like the following in your Pure scripts if you want to call one of the interface routines:

```plaintext
using pd;
```
(We mention in passing that, in the same fashion you can also put your own library scripts into the extra/pure/lib folder to make them available to all your Pure object scripts.)

```
extern char *pd_version_s()

Returns the Pd version number as a string. Note that this routine will only be available when a script is running inside Pd, so you can quickly check if that’s the case as follows:

let ok = stringp $ eval "extern char *pd_version_s(); pd_version_s;";
```

The ok variable will then be true iff the script is running inside Pd.

```
extern expr *pd_path()

Returns the Pd path (set in Pd’s Path dialog or via the -path command line option) as a list of directory names. This is useful if your Pure scripts need to locate files on the Pd search path.
```

```
extern char *pd_libdir()

Returns the Pd library dir (determined at runtime). This is useful if your Pure scripts need to access files in that directory.
```

```
extern expr *pd_getdir()

Returns the directory of the patch the current object is in. This is useful if a Pure object needs to access files in the patch directory. Please note that this function must be called during object creation or in the method calls of an object, so that it is clear what the current object is; otherwise the function will fail. Also note that the results may differ for different instances of the same object class, depending on which patches the objects are located in.
```

```
extern expr *pd_getfile()

Returns the name of the file that will be opened with the menu-open action (accessible by right-clicking on a Pure object and selecting Open). This is usually the Pure script of the object, if available, but this can be changed with pd_setfile() below. The function must be called during object creation or in the method calls of an object, so that it is clear what the current object is; otherwise the function will fail.
```

```
extern void pd_setfile(char *s)

Sets the name of the file to be opened with the menu-open action. By default, this is the Pure script of the object, if available; this function can be used to change the name of the file on a per-object basis. The function must be called during object creation or in the method calls of an object, so that it is clear what the current object is; otherwise the function will have no effect.
```

```
extern void pd_post(char *s)

Posts a message in the Pd main window. A trailing newline is added automatically. This is a convenience function which is equivalent to calling Pd’s post() (which is a varargs function) as post "%s" s.
```

```
extern void pd_error_s(char *s)

Like pd_post(), but prints an error message instead. If this routine is invoked from an object (i.e., during object creation or a method call) then Pd’s pd_error() function is called, which allows the object to be tracked down with Pd’s Find Last Error menu.
command. Otherwise (i.e., if the function is called at load time) Pd’s \texttt{error()} function is called which just outputs the message.

\textbf{extern double pd\_time()}

Retrieves the current Pd time as a double value in milliseconds, which is useful, in particular, when used in conjunction with the asynchronous message facility described under \texttt{Asynchronous Messages}.

\textbf{extern void pd\_send(char *sym, expr *x)}

Sends a message, specified as a Pure term \(x\), to the receiver given by the symbol \texttt{sym} (specified as a string). This is a no-op if the receiver doesn’t exist.

\textbf{extern void pd\_receive(char *sym)}

Prepares an object so that it can receive messages sent to the given symbol \texttt{sym}. This function must be called during object creation or method calls. It can be called for different symbols, as many times as needed. The messages are always delivered to the leftmost inlet, and the given symbol is applied to the original message, so that the receiver can figure out where the message came from.

\textbf{extern void pd\_unreceive(char *sym)}

Switches off receiving messages for the given symbol \texttt{sym}. Use this to undo the effects of a previous \texttt{pd\_receive} call.

\textbf{extern void pd\_configure(int in, int out)}

Changes the number of inlets and outlets of an object on the fly. This allows you to reconfigure a Pure object dynamically, if the number of inlets and outlets changes at runtime.

\textbf{extern void pd\_reload()}

Reload the calling object. This doesn’t actually reload any script files or libraries, it only recreates the object using its existing definition by re-evaluating its creation function. The object’s runtime function and the number of inlets and outlets are then updated accordingly, and if the object has any \texttt{pd\_save/pd\_restore} handlers, they will be invoked as well, see \texttt{Livecoding} above.

Usually you will only want to invoke this if the creation function picks up some global state (global variables, file contents, etc.). Otherwise nothing will actually change except that the local state of the object will be reinitialized.

This function never returns; it raises a special \texttt{__reload} exception which causes the calling object to be recreated later when it’s safe to do so. Thus this function must \textit{not} be invoked inside a Pure \texttt{catch} construct, unless you take care to pass on the \texttt{__reload} exception to \texttt{pd-pure} so that it can be handled there.

\textbf{extern expr *pd\_getbuffer(char *name)}

\textbf{extern void pd\_setbuffer(char *name, expr *x)}

\textbf{extern int pd\_getbuffersize(char *name)}

\textbf{extern void pd\_setbuffersize(char *name, int sz)}

Routines to access the Pd array (sample buffer) with the given name. These functions can be used to transfer audio data between Pd and Pure scripts; see \texttt{Reading and Writing Audio Data} above for an example.
pd_getbuffersize() and pd_setbuffersize() gets or sets the size of the given buffer, respectively.

pd_getbuffer() reads the contents of the buffer and returns it as a Pure vector (or fails if the array with the given name doesn’t exist).

pd_setbuffer() sets the contents of the buffer from the given Pure vector \( x \). If the size of the vector exceeds the size of the buffer, the former is truncated. Conversely, if the size of the buffer exceeds the size of the Pure vector, the trailing samples are unaffected. Note: The second argument of \( \text{pd_setbuffer}() \) can also be a pair \((i, x)\) denoting an offset \( i \) into the array at which the sample data is to be written, so that this routine allows you to overwrite any part of the array.
This is a digital audio interface for the Pure programming language. It currently includes the following modules:

- audio.pure: A PortAudio wrapper which gives you portable access to realtime audio input and output on a variety of different host APIs. This uses the well-known PortAudio library by Ross Bencina, Phil Burk et al, see http://www.portaudio.com/.

- fftw.pure: Compute real-valued FFTs of audio signals using Matteo Frigo’s and Steven G. Johnson’s portable and fast FFTW library (“Fastest Fourier Transform in the West”).

- sndfile.pure: Reading and writing audio files in various formats. This is a fairly straightforward wrapper for Erik de Castro Lopo’s libsndfile library, see http://www.mega-nerd.com/libsndfile/.

- samplerate.pure: Perform sample rate conversion on audio data. This uses another of Erik’s excellent libraries, libsamples (a.k.a. SRC), see http://www.mega-nerd.com/SRC/.

- realtime.pure: A little utility module which provides access to realtime scheduling to Pure programs. You may need this for low-latency realtime audio applications.

Documentation still needs to be written, so for the time being please read the source modules listed above and have a look at the examples provided in the distribution.

### 34.1 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-audio-0.6.tar.gz.

You need to have libportaudio (v19), libsndfile (1.x), libsamples (0.1.x) and libfftw3 (3.x) installed on your system. Any fairly recent version of these libraries should do. For the
realtime module you also need a POSIX threads library (libpthread) with the POSIX realtime thread extension; Linux, OSX and other Un*x systems should offer this.

The Pure wrappers contained in the distribution are for 64 bit POSIX systems. If you’re running a 32 bit system, or Windows, then you should regenerate them using ‘make generate’. This requires the header files portaudio.h, samplerate.h and sndfile.h (and pure-gen, of course). If you do this, check the includedir variables defined in the Makefiles, these need to point to the directories where the corresponding header files are to be found (the default is /usr/include).

Then just run ‘make’ to compile the package. If you’re lucky and everything compiles smoothly, you can install with ‘sudo make install’.

If you’re not so lucky, you can get help on the Pure mailing list, see http://groups.google.com/group/pure-lang.

### 34.2 License

pure-audio is Copyright (c) 2010 by Albert Graef, licensed under the 3-clause BSD license, see the COPYING file for details.

Please note that if you’re using these modules, you’re also bound by the license terms of the PortAudio, libsamplerate and libsndfile libraries they are based on, see the corresponding sources and websites for details.
pure-faust

Version 0.13, April 11, 2018

Albert Graef <aggraef@gmail.com>

This module lets you load and run Faust-generated signal processing modules in Pure. Faust (an acronym for Functional AUdio STreams) is a functional programming language for real-time sound processing and synthesis developed at Grame and distributed as GPL’ed software.

Note: As of Pure 0.45, there’s also built-in support for Faust interoperability in the Pure core, including the ability to inline Faust code in Pure programs; see Interfacing to Faust in the Pure manual. The built-in Faust interface requires a recent Faust version (2.0 or later, denoted using the “Faust2” moniker in the following). Both interfaces provide pretty much the same basic capabilities and should work equally well for most applications. In fact, as of version 0.5 pure-faust comes with a compatibility module which provides the pure-faust API on top of the built-in Faust interface, see the description of the faust2 module below for details.

35.1 Copying

Unless explicitly stated otherwise, this software is Copyright (c) 2009-2012 by Albert Graef. Please also see the source for the copyright and license notes pertaining to individual source files.

pure-faust is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

pure-faust is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.
35.2 Installation

Get the latest source from https://github.com/agraef/pure-lang/releases/download/pure-faust-0.13/pure-faust-0.13.tar.gz

Binary packages can be found at https://agraef.github.io/pure-lang/. To install from source, run the usual make & sudo make install. This requires Pure, of course (the present version will work with Pure 0.52 and later). The Makefile tries to guess the installation prefix under which Pure is installed. If it guesses wrong, you can tell it the right prefix with make prefix=/some/path. Or you can specify the exact path of the lib/pure directory with make libdir=/some/path; by default the Makefile assumes $(prefix)/lib/pure. The Makefile also tries to guess the host system type and set up some platform-specific things accordingly. If this doesn’t work for your system then you’ll have to edit the Makefile accordingly.

The Faust compiler is not required to compile this module, but of course you’ll need it to build the examples in the examples subdirectory and to compile your own Faust sources. You’ll need Faust 0.9.46 or later.

To compile Faust programs for use with this module, you’ll also need the pure.cpp architecture file. This should be included in recent Faust releases. If your Faust version doesn’t have it yet, you can find a suitable version of this file in the examples folder. Simply copy the file to your Faust library directory (usually something like /usr/local/lib/faust, /usr/local/share/faust with the latest Faust versions) or the directory holding the Faust sources to be compiled, and you should be set.

35.3 Usage

Once Faust and this module have been installed as described above, you should be able to compile a Faust dsp to a shared module loadable by pure-faust as follows:

$ faust -a pure.cpp -o mydsp.cpp mydsp.dsp
$ g++ -shared -o mydsp.so mydsp.cpp

Note that, by default, Faust generates code which does all internal computations with single precision. You can add the -double flag to the Faust command in order to use double precision instead. (In either case, all data will be represented as doubles on the Pure side.)

Also note that the above compile command is for a Linux or BSD system using gcc. Add -fPIC for 64 bit compilation. For Windows compilation, the output filename should be mydsp.dll instead of mydsp.so; on Mac OSX, it should be mydsp.dylib. There’s a Makefile and a shell script in the examples folder which both automate this process; the latter will also be included in recent Faust releases. Using the shell script, you can compile a Faust dsp simply as follows:
$ faust2pure mydsp.dsp

This will also print the name of the compiled module on stdout.

Once the module has been compiled, you can fire up the Pure interpreter and load the dsp as follows:

\texttt{\textgreater{} using faust;}
\texttt{\textgreater{} let dsp = faust\_init "mydsp" 48000;}
\texttt{\textgreater{} dsp;}
\texttt{\#<pointer 0xf09220>}

The \texttt{faust\_init} function loads the "mydsp.so" module (the .so suffix is supplied automatically) and returns a pointer to the Faust dsp object which can then be used in subsequent operations.

\textbf{Note:} \texttt{faust\_init} only loads the dsp module if it hasn't been loaded before. However, as of pure-faust 0.8, \texttt{faust\_init} also checks the modification time of the module and reloads it if the module was recompiled since it was last loaded. (This is for compatibility with Pure's built-in Faust interface which behaves in the same way.) If this happens, all existing dsp instances created with the old version of the module become invalid immediately (i.e., all subsequent operations on them will fail, except \texttt{faust\_exit}) and must be recreated.

The second parameter of \texttt{faust\_init}, 48000 in this example, denotes the sample rate in Hz. This can be an arbitrary integer value which is available to the hosted dsp (it's up to the dsp whether it actually uses this value in some way). The sample rate can also be changed on the fly with the \texttt{faust\_reinit} function:

\texttt{\textgreater{} faust\_reinit dsp 44100;}

It is also possible to create copies of an existing dsp with the \texttt{faust\_clone} function, which is quite handy if multiple copies of the same dsp are needed (a case which commonly arises when implementing polyphonic synthesizers):

\texttt{\textgreater{} let dsp2 = faust\_clone dsp;}

When you're done with a dsp, you can invoke the \texttt{faust\_exit} function to unload it (this also happens automatically when a dsp object is garbage-collected):

\texttt{\textgreater{} faust\_exit dsp2;}

Note that after invoking this operation the dsp pointer becomes invalid and must not be used any more.

In the following, we use the following little Faust program as a running example:

\begin{verbatim}
declare descr "amplifier";
declare author "Albert Graef";
declare version "1.0";
\end{verbatim}
gain = nentry("gain", 1.0, 0, 10, 0.01);
process = *(gain);

The `faust_info` function can be used to determine the number of input/output channels as well as the “UI” (a data structure describing the available control variables) of the loaded dsp:

```plaintext
> let n,m,ui = faust_info dsp;
```

Global metadata of the dsp is available as a list of key=>val string pairs with the `faust_meta` function. For instance:

```plaintext
> faust_meta dsp;
["descr"=>"amplifier","author"=>"Albert Graef","version"=>"1.0"]
```

To actually run the dsp, you’ll need two buffers capable of holding the required number of audio samples for input and output. For convenience, the `faust_compute` routine lets you specify these as Pure double matrices. `faust_compute` is invoked as follows:

```plaintext
> faust_compute dsp in out;
```

Here, `in` and `out` must be double matrices which have at least `n` or `m` rows, respectively (corresponding to the number of input and output channels of the Faust dsp). The row size of these matrices determines the number of samples which will be processed (if one of the matrices has a larger row size than the other, the extra elements are ignored). The `out` matrix will be modified in-place and also returned as the result of the call.

Some DSPs (e.g., synthesizers) only take control input without processing any audio input; others (e.g., pitch detectors) might produce just control output without any audio output. In such cases you can just specify an empty `in` or `out` matrix, respectively. For instance:

```plaintext
> faust_compute dsp {} out;
```

Most DSPs take additional control input. The control variables are listed in the “UI” component of the `faust_info` return value. For instance, suppose that there’s a `gain` parameter listed there, it might look as follows:

```plaintext
> controls ui!0;
hslider #<pointer 0x12780a4> [] ("gain",1.0,0.0,10.0,0.1)
```

The constructor itself denotes the type of control, which matches the name of the Faust builtin used to create the control (see the Faust documentation for more details on this). The `third` parameter is a tuple which indicates the arguments the control was created with in the Faust program. The `first` parameter is a C `double*` which points to the current value of the control variable. You can inspect and change this value with the `get_double` and `put_double` routines available in the Pure prelude. (Note that, for compatibility with the internal Faust interface which supports both single and double precision controls, you can also use the `get_control` and `put_control` functions instead.) Changes of control variables only take effect between different invocations of `faust_compute`. Example:
let gain = control_ref (controls ui!0);
get_double gain;
1.0
put_double gain 2.0;
()
faust_compute dsp in out;

Output controls such as hbargraph and vbargraph are handled in a similar fashion, only that
the Faust dsp updates these values for each call to faust_compute and Pure scripts can then
read the values with get_double or get_control.

The second parameter of a control description is a list holding the Faust metadata of the
control. This list will be empty if the control does not have any metadata. Otherwise you
will find some of key=>val string pairs in this list. It is completely up to the application how
to interpret the metadata, which may consist, e.g., of GUI layout hints or various kinds of
controller definitions. For instance, a MIDI controller assignment might look as follows in
the Faust source:

gain = nentry("gain[midi:ctrl 7]", 1.0, 0, 10, 0.01);

In Pure this information will then be available as:

control_meta (controls ui!0);
["midi"=>"ctrl 7"]

Let's finally have a closer look at the contents of the UI data structure. You will find that it
is actually a tree, similar to the directory tree of a hierarchical file system, which reflects the
layout of the controls in the Faust program. For instance:

ui;
vgroup [] ("mydsp",[nentry #<pointer 0x12780a4> [] ("gain",1.0,0.0,10.0,0.01)])

The leaves of the tree are the actual controls, while its interior nodes are so-called “control
groups”, starting from a root node which represents the entire dsp. There are different kinds
of control groups such as vgroup and hgroup; please check the Faust documentation for de-
tails. Control groups have a name and metadata just like individual controls, but there is no
control_ref component and the data stored at the node is the list of controls and subgroups
contained in the control group. The controls function returns a flat representation of the
controls in the UI tree as a list, omitting the group nodes of the tree:

controls ui;
[hslider #<pointer 0x12780a4> [] ("gain",1.0,0.0,10.0,0.1)]

We’ve already employed this function above to extract the gain control of our example dsp.
There’s a variation of this function which yields the full “pathnames” of controls in the UI
tree:

pcontrols ui;
[hslider #<pointer 0x12780a4> [] ("mydsp/gain",1.0,0.0,10.0,0.1)]

This is sometimes necessary to distinguish controls with identical names in different control
groups. There are two additional convenience functions which work with this flat representation of the UI data structure:

```pure
> let ctrls = ans;
> control_map ctrls;
("mydsp/gain"=>#<pointer 0x12780a4>}
> control_metamap ctrls;
("mydsp/gain"=>[])
```

The results are Pure records which provide convenient access to the pointers and metadata of the controls by their name.

Please note that, as of Pure 0.45, the UI access functions described above are actually provided by the faustui standard library module which gets included by the faust module. Further examples can be found in the examples subdirectory.

### 35.4 Faust2 Compatibility

As of version 0.5, pure-faust includes a Faust2 compatibility module which lets you use the pure-faust API on top of Pure’s new Faust bitcode interface, using the same operations as described under Usage above. This module is invoked with the following import clause:

```pure
using faust2;
```

To instantiate a Faust dsp using the faust2 interface, you’ll have to compile the Faust program to LLVM bitcode format. The easiest way to do this is to use the faust2pure script with the -bitcode option. Please see the Interfacing to Faust section in the Pure manual for details.

Note that only one of the faust and faust2 modules may be imported into a program; trying to use both modules in the same program will not work. Also note that the faust2 module requires Faust2 and a fairly recent Pure version to work, whereas the faust module works with both current Faust (Faust2) and older Faust versions and doesn’t rely on the Faust bitcode loader (only the pure.cpp architecture is needed).

### 35.5 Acknowledgements

Many thanks to Yann Orlarey at Grame, the principal author of Faust!
Chapter 36

pure-liblo

Version 0.9, April 11, 2018
Albert Gräf <aggraef@gmail.com>

36.1 Copying

Copyright (c) 2009 by Albert Graef.
pure-liblo is free software: you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.
pure-liblo is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.
You should have received a copy of the GNU Lesser General Public License along with this program. If not, see <http://www.gnu.org/licenses/>.

36.2 Description

This is a quick and dirty Pure wrapper for the liblo library by Steve Harris and others, which implements Berkeley’s Open Sound Control (OSC) protocol.
OSC is a protocol for exchanging data between multimedia devices and software across the network (TCP, UDP and UNIX domain sockets are supported as the transport layer). It is also useful as a general communication mechanism for both hard- and software. In difference to the plain socket interface (on which it builds), OSC provides you with an efficient means to send around binary data packets along with the corresponding type and timing information, which makes it well-suited for both realtime and non-realtime applications.
The OSC protocol is standardized and is supported by an abundance of different implementations, which includes controller hardware of all sorts and computer music software like
CSound, Pd and SuperCollider. Lots of implementations exist for different programming languages. liblo aims to provide a lightweight and ubiquitous OSC implementation for the C programming language.

The `lo.pure` module provides a fairly straight wrapper of the C library. A more high-level and Purified interface is available in `osc.pure`. Most of the time, you’ll want to use the latter for convenience, but if you need utmost flexibility then it is worth having a look at `lo.pure`, too.

- Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-liblo-0.9.tar.gz.
- To install, run `make` and `sudo make install`. This will try to guess your Pure installation directory; if it guesses wrong, you can set the `prefix` variable accordingly, see the Makefile for details.
- You can also regenerate the wrapper by running `make generate`; this requires the `pure-gen` utility and the liblo headers. The present version was generated from liblo 0.26. If your liblo version differs from that then it’s always a good idea to run `make generate`.
- Have a look at `lo.pure` and `osc.pure` for a description of the API provided to Pure programmers.
- The examples folder contains some Pure code which illustrates how to use these modules.
Chapter 37

pure-lilv: Pure Lilv Interface

Version 0.5, April 11, 2018
Albert Gräf <aggraef@gmail.com>

37.1 Copying

pure-lilv is Copyright (c) 2014 by Albert Gräf. It is distributed under a 3-clause BSD license, please check the COPYING file included in the distribution for details.

37.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-lilv-0.5.tar.gz.

Run make to compile the module and sudo make install to install it in the Pure library directory. To uninstall the module, use sudo make uninstall. There are a number of other targets (mostly for maintainers), please see the Makefile for details.

make tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually. In particular, make install prefix=/usr sets the installation prefix.

37.3 Description

This package provides a Pure module for David Robillard’s Lilv, a library for LV2 plugin host writers. LV2 is the new Linux audio plugin standard (LADSPA successor) which aims to be portable and extensible. Lilv makes it possible to load LV2 plugins in audio and other multimedia software. It is provided as a comprehensive and well-tested reference implementation for LV2 plugin hosts, so that authors of multimedia software don’t have to craft their own (and often incomplete or bug-ridden) implementations of the LV2 plugin API.
This module is still under development, but we already offer operations to retrieve information about the LV2 plugins installed on a system, and to instantiate and run most basic plugins. Support for MIDI input and output and handling LV2 presets and plugin state is also available. More work is still needed in order to support more exotic event types such as transport state and tempo changes, and any other extensions which may be required to run more advanced plugins. We’re still trying to figure these out, so if you notice anything that’s missing in the current implementation then please submit a feature request.

Documentation still needs to be written. For the time being, please refer to the lilv.pure script for a description of the programming interface, and to the scripts in the examples folder for examples showing how to use the operations provided by this module. Specifically, have a look at the lilv_examp.pure script which illustrates most the API functions and how they are used in a Pure script. There’s also a fairly complete software synthesizer example, synth.pure, which shows how to run instrument and effect plugins in a synth/effects chain in order to synthesize audio from MIDI input. Another complete example is the lv2plugin~ host for Pd which is written entirely in Pure; you can find this at https://bitbucket.org/agraef/pd-lv2plugin.

Here’s a brief excerpt from lilv_examp.pure which shows the necessary steps involved in running an LV2 audio plugin with Pure:

```plaintext
// Import the module.
using lilv;

// Load the LV2 world state.
let world = lilv::world;

// Instantiate a plugin.
let p = lilv::plugin world "http://faust-lv2.googlecode.com/amp" 44100 64;

// Get some information about the plugin (number of audio inputs and // outputs, port descriptions).
let n,m = lilv::num_audio_inputs p, lilv::num_audio_outputs p;
let ports = [i, lilv::port_info p i | i = 0..lilv::num_ports p-1];

// Create some audio buffers for input and output.
let in = dmatrix {0,1,0,-1,0,1,-1,0;0,1,0,-1,0,1,-1,0};
let out = dmatrix (2,8);

// Activate the plugin.
lilv::activate p;

// Run some samples through the plugin.
lilv::run p in out;

// Set a control value.
lilv::set_control p 2 10;

// Compute some more samples.
lilv::run p in out;

// Get the values of some output controls.
map (lilv::get_control p) [4,5];
```
// Send a MIDI message.
lilv::set_midi p 10 [{0xb0, 7, 127}];

// Compute some more samples.
lilv::run p in out;
38.1 Copying

pure-lv2 is Copyright (c) 2014 by Albert Gräf. It is distributed under a 3-clause BSD license, please check the COPYING file included in the distribution for details.

38.2 Installation

Get the latest source from https://bitbucket.org/purelang/pure-lang/downloads/pure-lv2-0.2.tar.gz.

Make sure that you have the latest Pure version installed. Pure 0.60 or later is needed.

Run `make` to compile and `sudo make install` to install the module. This installs the lv2.pure module and the source of the LV2 plugin wrapper (lv2pure.c, lv2pure.h) in the Pure library directory, and the pure2lv2 script in the bin directory, under the same installation prefix as the Pure interpreter. To uninstall the module, use `sudo make uninstall`. There are a number of other targets (mostly for maintainers), please see the Makefile for details.

`make` tries to guess your Pure installation directory and platform-specific setup. If it gets this wrong, you can set some variables manually, please see the Makefile for details.

38.3 Description

LV2 is the new Linux audio plugin standard (successor of the venerable LADSPA standard) which aims to be portable and extensible. LV2 plugins can process any combination of audio, MIDI and control data in order to implement various kinds of real-time signal processing.
modules for use in digital audio and MIDI software such as Ardour and Qtractor. A companion module is available which lets you implement LV2 plugin hosts in Pure, see pure-lilv: Pure Lilv Interface. Support for Miller Puckette’s graphical computer music and multimedia software Pd is available through the author’s lv2plugin~ external. Moreover, stand-alone LV2 hosts such as jalv can be used to interface with other software which doesn’t support LV2 directly, via the Jack audio connection kit.

This package provides a generic LV2 plugin wrapper for Pure which can be linked with batch-compiled Pure scripts to obtain LV2 plugin modules. For convenience, a shell script named pure2lv2 is included, which lets you compile the plugin and turn it into a complete LV2 bundle (consisting of an LV2 plugin manifest and the plugin binary), ready to be loaded by any LV2 host. The package also includes an lv2.pure module which provides the operations needed to implement the functionality of a plugin, such as functions to read and write LV2 port data in Pure.

Our implementation supports all standard LV2 port types (including MIDI via LV2 atom ports) and should thus be able to work with most LV2 hosts right out of the box. Experimental support for the LV2 time extension is also available, so that MIDI plugins written in Pure can obtain musical time and position data if the host supports this; please check lv2.pure for details. The package includes several examples which demonstrate how to write LV2 plugins of various kinds in Pure, specifically:

- pure_amp.pure shows how to do basic audio and control processing in order to amplify an incoming audio signal.
- pure_transp.pure demonstrates how to implement a simple MIDI processing module which transposes incoming MIDI notes.
- pure_metro.pure shows how to implement a MIDI metronome by making use of the musical time and tempo data provided by the LV2 time extension (this currently requires Ardour to work).

Please also check the Usage section below for information on how to run the pure2lv2 script.

### 38.4 Requirements and Limitations

Our implementation uses LV2’s dynamic manifests, so that the plugin manifest, which describes the ports and other properties of the plugin, can be included in the plugin module. This makes things easier, but requires an LV2 host which supports the dynamic manifest extension (most LV2 hosts nowadays do; this includes all the hosts we mentioned above).

As the Pure runtime isn’t thread-safe yet, our implementation effectively serializes the plugin callbacks (invocations of the plugin function) across all Pure plugins running inside a host. While this won’t make a difference for single-threaded LV2 hosts such as jalv and Pd, it also makes the Pure plugins work reliably in heavily multi-threaded hosts such as Ardour. However, the serialization of callbacks may become a major bottleneck if a multi-threaded host runs many Pure plugins concurrently on a multi-processor machine. At present there is no way around this, but hopefully this limitation will go away in the not-too-distant future when the Pure runtime becomes thread-safe.
38.5 Usage

A summary of the command syntax and options of the pure2lv2 script can be printed with purelv2 -h. Usually the script is invoked simply as pure2lv2 myplugin.pure, where myplugin.pure is the Pure script implementing the plugin. The plugin script must provide two functions in order to implement the functionality of the plugin:

- The **manifest** function returns the port descriptions from which the plugin manifest is created when the LV2 host performs plugin discovery. This may be implemented either as a parameter-less function or a global variable in the Pure script. In either case it should return the list of port descriptions in a format described in the lv2.pure module.

- The **plugin** function implements the plugin itself. It gets invoked with a pointer object representing the plugin data which can be passed to the operations in the lv2.pure module. Often the plugin will actually be implemented as a closure which also encapsulates the local state maintained by the plugin; please check the included examples for details. At runtime, the plugin function gets invoked repeatedly with an additional parameter, either a truth value denoting a change in the activation status, or the value () to indicate that a block of samples (and/or MIDI messages and control data) is to be processed.

Please check the included examples to get an idea how the plugin scripts look like. Here is a simple example (an abridged version of pure_amp.pure) which multiplies an incoming audio signal with a volume control:

```pure
using lv2;

manifest = [(
  "vol", "Volume", lv2::controlin, 0.5, 0.0, 1.0),
  ("audioin", lv2::audioin),
  ("audioout", lv2::audioout)];

plugin self () = () when
  // Process a block of samples.
  vol = lv2::get_port self 0; // control value from port #0 (control input)
  wav = lv2::get_port self 1; // sample data from port #1 (audio input)
  // Multiply the sample data with the vol control value and output the
  // resulting wave on port #2 (audio output).
  lv2::set_port self 2 (map (*vol) wav);
end;
```

Running pure2lv2 myplugin.pure turns the plugin script into an LV2 bundle, which will be written to myplugin.lv2 by default (i.e., using the same basename as the plugin script). You can also specify a different name and path for the bundle directory with the -o (or --output) option, and a custom URI prefix for the bundle with the -u (or --uriprefix) option. Before you can use the plugin with your LV2 hosts, you still have to move the bundle directory to a directory on your LV2_PATH (unless you already specified a suitable target path with -o). The examples folder in the source package contains a GNU Makefile which shows how to automate this process.

Normally the Pure code of the plugin will be compiled to a native object file which gets linked directly into the plugin binary. However, there’s also a -s (or --script) option which
copies the source script (along with any additional source files specified after the plugin
script on the command line) to the bundle directory instead, from where it will be loaded
dynamically when the plugin is used. This increases load times, sometimes substantially,
since the Pure interpreter will have to JIT-compile the Pure script every time the host starts
up and loads the plugins. But it also reduces turnaround times since you can easily change
the plugin script right inside the bundle, without having to run pure2lv2 in between; this
may be convenient when developing and testing a plugin.
Chapter 39

pure-midi

Version 0.6, April 11, 2018

Albert Graef <aggraef@gmail.com>

This is a MIDI interface for the Pure programming language (Pure 0.45 or later is required). It includes the following modules:

- **midi.pure**: A PortMidi/PortTime wrapper which gives you portable access to realtime MIDI input and output. This uses PortMidi (by Roger B. Dannenberg et al) from the PortMedia project, see [http://portmedia.sourceforge.net/](http://portmedia.sourceforge.net/).

- **midifile.pure**: Reading and writing standard MIDI files. This is based on David G. Slomin’s light-weight midifile library, which comes bundled with the pure-midi sources.

Documentation still needs to be written, so for the time being please read the source modules listed above and have a look at the examples provided in the distribution.

### 39.1 Installation

You need to have the PortMidi library installed on your system. This release was tested with PortMidi 2.00 (I recommend using the svn version of PortMidi, since it fixes some 64 bit compilation problems). If you have to use some earlier PortMidi version then you may have to fiddle with portmidi.pure and/or midi.pure to make it work. (You can also just regenerate the wrapper by copying portmidi.h and porttime.h from your PortMidi installation to the pure-midi source directory and running ‘make generate’. This requires pure-gen. See the toplevel Makefile for details.)

Run ‘make’ to compile the package. If you’re lucky and everything compiles smoothly, you can install with ‘sudo make install’.
If you’re not so lucky, you can get help on the Pure mailing list, see http://groups.google.com/group/pure-lang.

NOTE: You may also want to install the related pure-audio package. In particular, pure-audio also provides realtime.pure, a little utility module which gives Pure programs access to realtime scheduling.

### 39.2 License

pure-midi is Copyright (c) 2010 by Albert Graef, licensed under the 3-clause BSD license, see the COPYING file for details.

For convenience, I’ve bundled some (BSD-licensed or compatible) source files from other packages with this release. portmidi.h and porttime.h are from PortMidi 2.00 (http://portmedia.sourceforge.net/) which is

Copyright (c) 1999-2000 Ross Bencina and Phil Burk Copyright (c) 2001-2006 Roger B. Dannenberg

midifile.c and midifile.h in the midifile subdirectory are from “Div’s midi utilities” (http://public.sreal.com:8000/~div/midi-utils/) which is

Copyright (c) 2003-2006 David G. Slomin

Please see portmidi.h and midifile.h for the pertaining copyrights and license conditions.
40

Installing Pure (and LLVM)

Version 0.68, April 11, 2018

Albert Graef <aggraef@gmail.com>
Eddie Rucker <erucker@bmc.edu>

These instructions explain how to compile and install LLVM (which is the compiler back-
end required by Pure) and the Pure interpreter itself. The instructions are somewhat biased
towards Linux and other Unix-like systems; the System Notes section at the end of this file
details the tweaks necessary to make Pure compile and run on various other platforms. More
information about installing LLVM and the required LLVM source packages can be found at

Pure is known to work on Linux, FreeBSD, NetBSD, Mac OS X and MS Windows, and should
compile (with the usual amount of tweaking) on all recent UNIX/POSIX- based platforms.
Pure should compile out of the box with reasonably recent versions of either gcc or clang.
You’ll also need a Bourne-compatible shell and GNU make, which are also readily available
on most platforms. For Windows compilation we support the Mingw version of gcc along
with the MSYS environment.

A binary package in msi format is provided for Windows users in the download area at
https://github.com/agraef/pure-lang/releases. Information about ports and packages for
other (UNIX-like) systems is provided at the same location.

40.1 Quick Summary

Here is the executive summary for the impatient. This assumes that you’re using LLVM 3.4
and Pure 0.68, please substitute your actual version numbers in the commands given below
as needed.
Note: If you're reading this documentation online, then the Pure version described here most likely is still under development, in which case you can either grab the latest available release, or install from the development sources instead (see Installing From Development Sources below).

Prerequisites: gcc, GNU make, flex/bison (development sources only), libtldl, libgmp and libmpfr (including header files for development), wget (for downloading and installing the online documentation), GNU emacs (if you want to use Emacs Pure mode). These should all be available as binary packages on most systems.

You’ll also need LLVM and, of course, Pure. The LLVM 3.4 and Pure 0.68 tarballs are available here:

https://github.com/agraef/pure-lang/releases/download/pure-0.68/pure-0.68.tar.gz
http://llvm.org/releases/3.4/llvm-3.4.src.tar.gz
http://llvm.org/releases/3.4/clang-3.4.src.tar.gz
http://llvm.org/releases/3.4/dragonegg-3.4.src.tar.gz

Note: The present Pure version requires an LLVM version that still supports the “old” (pre-MCJIT) just-in-time compiler back-end (JIT). This means that the latest supported LLVM release is 3.5.2, which was released in April 2015. Earlier versions in the 3.x series should still work fine as well, if you can make them compile on your system. The following instructions assume that you use the very stable LLVM 3.4 release, otherwise you’ll have to adjust the commands in the instructions accordingly.

Installing LLVM and clang (the latter is optional but recommended):

$ tar xfvz llvm-3.4.src.tar.gz
$ tar xfvz clang-3.4.src.tar.gz && mv clang-3.4 llvm-3.4/tools/clang
$ cd llvm-3.4
$ ./configure --enable-shared --enable-optimized --enable-targets=host-only
$ make && sudo make install

Be patient, this takes a while...

You may want to leave out --enable-shared to install LLVM as static libraries only, and --enable-targets=host-only if you want to enable cross compilation for all supported targets in LLVM. (With some older LLVM versions you may also have to add --disable-assertions --disable-expensive-checks to disable stuff that makes LLVM very slow and/or breaks it on some systems.) Also, if you’re still running gcc 4.5 or 4.6, you may want to install the LLVM “DragonEgg” plugin for gcc, which provides LLVM bitcode compilation for languages other than C/C++. Please check the dragonegg section below for details.

Installing Pure:
$ tar xfvz pure-0.68.tar.gz
$ cd pure-0.68
$ ./configure --enable-release
$ make && sudo make install

Depending on your system you may have to run a utility to announce the shared LLVM and Pure libraries to the dynamic loader. E.g., on Linux:

$ sudo /sbin/ldconfig

It is also recommended that you run the following to make sure that the Pure interpreter works correctly on your platform (see step 5 below for details):

$ make check

The following is optional, but if you want to read the online documentation in the interpreter or in Emacs Pure mode, you’ll have to download and install the documentation files:

$ sudo make install-docs

This needs the wget program. You can also download and install the pure-docs tarball manually in the usual way, e.g.:

$ tar xfvz pure-docs-0.68.tar.gz
$ cd pure-docs-0.68
$ sudo make install

That’s it, Pure should be ready to go now:

$ pure

Uninstalling:

$ cd pure-0.68
$ sudo make uninstall
$ cd ../llvm-3.4
$ sudo make uninstall

Please see below for much more detailed installation instructions.

### 40.2 Basic Installation

The basic installation process is as follows. Note that steps 1-3 are only required once. Steps 2-3 can be avoided if binary LLVM packages are available for your system (but see the caveats about broken LLVM packages on some systems below). Additional instructions for compiling Pure from the latest repository sources can be found in the Installing From Development Sources section below. Moreover, you can refer to the Other Build And Installation Options section below for details about various options available when building and installing Pure.

**Step 1.** Make sure you have all the necessary dependencies installed (-dev denotes corresponding development packages):
Pure Language and Library Documentation, Release 0.68

- GNU make, GNU C/C++ and the corresponding libraries;
- the GNU multiprecision library (libgmp, -dev) or some compatible replacement (see comments below);
- the GNU multiprecision floating point library (libmpfr, -dev);
- the PCRE library (libpcre, -dev), if you want Perl-compatible regex support (see below);
- GNU readline (libreadline, -dev) or some compatible replacement (only needed if you want command line editing support in the interpreter; see comments below).
- GNU Emacs (if you want to use the Emacs Pure mode).
- GNU TeXmacs (if you want to use the TeXmacs Pure plugin).

In addition, the following will be required to compile the development version (see the Installing From Development Sources section below):

- autoconf and automake;
- flex and bison;
- git (needed to fetch the development sources).

The following may be required to build some LLVM versions:

- GNU ltdl library (libltdl, -dev).

All dependencies are available as free software. Here are some links if you need or want to install the dependencies from source:

- Autoconf: http://www.gnu.org/software/autoconf
- Automake: http://www.gnu.org/software/automake
- GNU C/C++: http://gcc.gnu.org
- GNU make: http://www.gnu.org/software/make
- Flex: http://flex.sourceforge.net
- Bison: http://www.gnu.org/software/bison
- GNU Emacs: http://www.gnu.org/software/emacs
- GNU TeXmacs: http://savannah.gnu.org/projects/texmacs
- GNU ltdl (part of the libtool software): http://www.gnu.org/software/libtool

Git can be obtained from https://git-scm.com/. A number of graphical frontends can be found there as well. Windows users may also want to check TortoiseGit, see https://tortoisegit.org/.

The GNU multiprecision library or some compatible replacement is required for Pure’s big-int support. Instead of GMP it’s also possible to use MPIR. You can find these here:

- GMP: http://www.gnu.org/software/gmp
If you have both GMP and MPIR installed, you can specify `--with-mpir` when configuring Pure to indicate that Pure should be linked against MPIR. Note that using this option might cause issues with some Pure modules which explicitly link against GMP. If you run into any such problems then you should build MPIR with the `--enable-gmpcompat` configure option so that it becomes a drop-in replacement for GMP (in this case the `--with-mpir` option isn’t needed when configuring Pure).

In addition, Pure 0.48 and later also require the GNU multiprecision floating point library:

- **MPFR:** [http://www.mpfr.org](http://www.mpfr.org)

(Pure doesn’t really have built-in support for MPFR numbers, this is provided through a separate pure-mpf addon module instead, please check the Pure website for details. However, there is now some support for printing both GMP and MPFR numbers in the printf and scanf functions of the system module, for which the MPFR library is needed.)

To make interactive command line editing work in the interpreter, you’ll also need GNU readline or some compatible replacement such as BSD editline/libedit:

- BSD editline/libedit: [http://www.thrysoee.dk/editline](http://www.thrysoee.dk/editline)

We recommend GNU readline because it’s easier to use and has full UTF-8 support, but in some situations BSD editline/libedit may be preferable for license reasons or because it’s what the operating system provides. Pure’s configuration script automatically detects the presence of both packages and also lets you disable readline and/or editline support using the `--without-readline` and `--without-editline` options.

Pure normally uses the system’s POSIX regex functions for its regular expression support (regex module). Instead, you can also build it with support for Perl-style regular expressions. This is done by linking in the POSIX compatibility layer of the PCRE library:

- **PCRE:** [http://www.pcre.org/](http://www.pcre.org/)

Please note that the PCRE support is still experimental and currently disabled by default. Configuring with `--with-pcre` enables it. Also note that at present this is only available as a compile-time switch; to change the regex library used by the Pure runtime you need to recompile the interpreter.

**Step 2.** Get and unpack the LLVM sources.

You can find these at [http://llvm.org/releases/download.html](http://llvm.org/releases/download.html).

You only need the LLVM tarball which contains the LLVM library as well as most of the LLVM toolchain. LLVM 3.5.2 is the latest supported release at the time of this writing. LLVM versions 2.5 thru 3.5 have all been tested and are known to work with Pure. We really recommend using LLVM 3.0 or later, however, because LLVM has improved considerably in recent releases. (Support for older versions may be dropped in the future.)

At this point we also recommend getting an LLVM-capable C/C++ compiler. This is completely optional, but you’ll need it to take advantage of the new bitcode loader in Pure 0.44.
and later. The easiest way to go is to take the clang tarball which corresponds to your LLVM version, unpack its contents into the LLVM tools directory and rename the clang-x.y directory to just clang. The clang compiler will then be built and installed along with LLVM. On older systems, you can also use llvm-gcc or dragonegg instead, please see Installing an LLVM-capable C/C++ Compiler below for further details.

Note: Some (older) Linux and BSD distributions provide LLVM packages and ports which are compiled with wrong configure options and are thus broken. If the Pure interpreter segfaults on startup or fails its test suite (make check) then you should check whether there’s a newer LLVM package available for your system, or compile LLVM yourself.

Step 3. Configure, build and install LLVM as follows (assuming LLVM 3.4):

$ cd llvm-3.4
$ ./configure --enable-shared --enable-optimized --enable-targets=host-only
$ make
$ sudo make install

LLVM 2.7 and earlier may also require the flags --disable-assertions --disable-expensive-checks to disable some features which make LLVM slow and/or buggy on some systems. With LLVM 2.8 and later these options aren’t needed any more.

Note that the --enable-shared option builds and installs LLVM as a shared library, which is often preferable if you’re running different LLVM-based tools and compilers on your system. This requires LLVM 2.7 or later and may be broken on some systems. You can always leave out that option, in which case LLVM will be linked statically into the Pure runtime library. (You can also force Pure to be linked statically against LLVM even if you have the shared LLVM library installed, by configuring Pure with the --with-static-llvm flag. This may be useful if you plan to deploy the Pure runtime library on systems which don’t have LLVM installed.)

Also note that the configure flags are for an optimized (non-debug) build and disable all compilation targets but the one for your system. You might wish to play with the configure options, but note that some options (especially --enable-expensive-checks) can make LLVM very slow and may even break the Pure interpreter on some systems.

Step 4. Get and unpack the Pure sources.

These can be downloaded from https://agraef.github.io/pure-lang. The latest source tarballs can always be found in the “Downloads” section.

Step 5. Configure, build and install Pure as follows:

$ cd pure-0.68
$ ./configure --enable-release
$ make
$ sudo make install

The --enable-release option configures Pure for a release build. This is recommended for maximum performance. If you leave away this option then you’ll get a default build which
includes debugging information and extra runtime checks useful for the Pure maintainers, but also runs considerably slower.

To find out about other build options, you can invoke configure as `.configure --help`.

The `sudo make install` command installs the pure program, the runtime.h header file, the runtime library libpure.so, a Pure pkg-config file (pure.pc) and the library scripts in the appropriate subdirectories of `/usr/local`; the installation prefix can be changed with the `--prefix` configure option, see Other Build And Installation Options for details. (The runtime.h header file is not needed for normal operation, but can be used to write C/C++ extensions modules or embed Pure in your C/C++ applications.)

In addition, if the presence of GNU Emacs was detected at configure time, then by default pure-mode.el and pure-mode.elc (as well as the corresponding flycheck package) will be installed in the Emacs site-lisp directory. make tries to guess the proper location of the site-lisp directory, but if it guesses wrong or if you want to install in some custom location then you can also set the elispdir make variable accordingly. If you prefer, you can also disable the automatic installation of the elisp files by running configure with `.configure --without-elisp`. (In that case, it's still possible to install the elisp files manually with make install-el install-elc.)

Similarly, if you have GNU TeXmacs on your system and configure can locate it, the corresponding Pure plugin will be installed into the TeXmacs plugins directory. make tries to guess the proper location of the TeXmacs plugins directory, but if it guesses wrong or if you want to install in some custom location then you can also set the tmdir make variable accordingly. If you prefer, you can also disable the automatic installation of the TeXmacs plugin by running configure with `.configure --without-texmacs`. (In that case, it's still possible to install the plugin manually with make install-tm.)

On some systems you have to tell the dynamic linker to update its cache so that it finds the Pure runtime library. E.g., on Linux this is done as follows:

```
$ sudo /sbin/ldconfig
```

After the build is complete, you can (and should) also run a few tests to check that Pure is working correctly on your computer:

```
$ make check
```

(This can be done before actually installing Pure, but make sure that you first run `ldconfig` or similar if you installed LLVM as a shared library, otherwise make check may fail simply because the LLVM library isn’t found.)

If all is well, all tests should pass. If not, the test directory will contain some `.diff` files containing further information about the failed tests. In that case please zip up the entire test directory and mail it to the author, post it on the Pure mailing list, or enter a bug report at https://github.com/agraef/pure-lang/issues. Also please include precise information about your platform (operating system and cpu architecture) and the Pure and LLVM versions and/or source revision numbers you’re running.

Note that make check executes the run-tests script which is generated at configure time. If
necessary, you can also run individual tests by running run-tests directly (e.g., ./run-tests test/test020.pure test/test047.pure) or rerun only the tests that failed on the previous invocation (./run-tests -f or, equivalently, make recheck).

Also note that MSYS 1.0.11 or later (or at least the diffutils package from that version) is required to make make check work on Windows. Also, under MS Windows this step is expected to fail on some math tests in test020.pure; this is nothing to worry about, it just indicates that some math routines in Microsoft’s C library aren’t fully POSIX-compatible. The same applies to some BSD systems.

If Pure appears to be broken on your system (make check reports a lot of failures), it’s often because of a miscompiled LLVM. Please review the instructions under step 3, and check the System Notes section to see whether your platform is known to have issues and which workarounds may be needed. If all that doesn’t help then you might be running into LLVM bugs and limitations on not-so-well supported platforms; in that case please also report the results of make check as described above, so that we can try to figure out what is going on and whether there’s a fix or workaround for the problem.

Note: If you have one of the LLVM C/C++ compilers installed (see Installing an LLVM-capable C/C++ Compiler), you can use those to compile Pure by passing the appropriate compiler names on the configure line:

```
$ ./configure --enable-release CC=clang CXX=clang++
```

Or, when using llvm-gcc:

```
$ ./configure --enable-release CC=llvm-gcc CXX=llvm-g++
```

llvm-gcc 4.2 and clang 2.8 or later should build Pure cleanly and pass all checks.

---

**Step 6.** Download and install the online documentation as follows:

```
$ sudo make install-docs
```

This isn’t necessary to run the interpreter, but highly recommended, as it gives you a complete set of manuals in html format which covers the Pure language and interpreter, the standard library, and all addon modules available from the Pure website. You can read these manuals with the help command in the interpreter. You also need to have a html browser installed to make this work. By default, the interpreter assumes w3m (a text-based browser), you can change this by setting the BROWSER or the PURE_HELP variable accordingly.

The install-docs target requires a working Internet connection and the wget command. Instead, you can also download the pure-docs-0.68.tar.gz tarball manually and then install the documentation from the downloaded tarball in the usual way:

```
$ tar xfvz pure-docs-0.68.tar.gz
$ cd pure-docs-0.68
$ sudo make install
```

As a bonus, downloading the package manually also gives you the documentation in pdf...
format (900+ pages), so that you can print it if you like. In addition, as of version 0.56 the tarball also contains the documentation in TeXmacs format so that you can read it inside TeXmacs (see TeXmacs Plugin below). After unpacking the tarball and installing the html documentation, you can install the TeXmacs-formatted documentation as follows:

```
$ sudo make install-tm
```

**Step 7.** The Pure interpreter should be ready to go now.

Run Pure interactively as:

```
$ pure
```

Loaded prelude from /usr/lib/pure/prelude.pure.

Check that it works:

```
> 6*7;
42
```

Read the online documentation:

```
> help
```

Exit the interpreter (you can also just type the end-of-file character at the beginning of a line, i.e., Ctrl-D on Unix):

```
> quit
```

You can also run the interpreter from GNU Emacs and GNU TeXmacs (see below), and for Windows there is a nice GUI application named “PurePad” which makes it easy to edit and run your Pure scripts.

### 40.3 Emacs Pure Mode

This step is optional, but if you’re friends with Emacs then you should definitely give Pure mode a try. This is an Emacs programming mode which turns Emacs into an advanced IDE to edit and run Pure programs. If Emacs was detected by configure then after running make and sudo make install the required elisp files should already be installed in the Emacs site-lisp directory (unless you specifically disabled this with the `--without-elisp` configure option).

Note: make tries to guess the Emacs installation prefix. If it gets this wrong, you can also set the make variable elispdir to point to your site-lisp directory. (In fact, you can specify any directory on Emacs’ loadpath for elispdir.)
Before you can use Pure mode, you still have to add some stuff to your .emacs file to load the mode at startup. A minimal setup looks like this:

```
(require 'pure-mode)
(setq auto-mode-alist
      (cons '("\l.pure\(rc\)?$" . pure-mode) auto-mode-alist))
(add-hook 'pure-mode-hook 'turn-on-font-lock)
(add-hook 'pure-eval-mode-hook 'turn-on-font-lock)
```

This loads Pure mode, associates the .pure and .purerc filename extensions with it, and enables syntax highlighting.

Other useful options are described at the beginning of the pure-mode.el file. In particular, we recommend installing emacs-w3m and enabling it as follows in your .emacs file, so that you can read the online documentation in Emacs:

```
(require 'w3m-load)
```

Also, you can enable code folding by adding this to your .emacs:

```
(require 'hideshow)
(add-hook 'pure-mode-hook 'hs-minor-mode)
```

These lines should come before the loading of Pure mode in your .emacs, so that Pure mode can adjust accordingly.

Once Emacs has been configured to load Pure mode, you can just run it with a Pure file to check that it works, e.g.:

```
$ emacs examples/hello.pure
```

The online help about Pure mode can be read with C-h m. The Pure documentation can be accessed in Pure mode with C-c h.

Last but not least, support for flycheck, the on-the-fly syntax checker is available through a separate flycheck-pure.el package, which can be enabled in your .emacs as follows:

```
(require 'flycheck-pure)
(eval-after-load 'flycheck
   '(add-hook 'flycheck-mode-hook #'flycheck-pure-setup))
```

You need to have flycheck installed to make this work (it’s available in MELPA). Also, the Pure interpreter needs to be in your PATH or flycheck will not be able to find it.

This is highly recommended, because flycheck will warn you about syntax errors, undeclared identifiers, etc. immediately – anything which can be found without actually executing the program. flycheck does this by continually running pure --check on your program while you’re editing it. By default, flycheck will flag both errors and warnings by invoking the Pure interpreter with the -w option. If you only want to see real compilation errors, you can turn this off by setting the flycheck-pure-warnings variable to nil:

```
(setq flycheck-pure-warnings nil)
```
Also note that flycheck will not run on a buffer unless you specifically enable it (in which case you’ll see the FlyC indicator in the mode line). However, you can also enable flycheck globally so that it automatically runs in every buffer with a mode that has an associated checker. To these ends, add the following line to your .emacs:

```
(add-hook 'after-init-hook #'global-flycheck-mode)
```

Please check the flycheck website for more information.

### 40.4 TeXmacs Plugin

Pure 0.56 has full support for running Pure as a session in GNU TeXmacs. This is triggered by the `--texmacs` option of the interpreter. If TeXmacs was detected by configure then after running make and `sudo make install` the required plugin files should already be installed in the system-wide TeXmacs plugins directory and you should be able to find Pure in TeXmacs’ Insert / Session and Document / Scripts menus. TeXmacs help is also included; after installation this should be available with the Help / Plug-ins / Pure menu option. Or you can just go and read the TeXmacs documents (.tm files) in texmacs/plugins/pure/doc included in the distribution.

Note: make tries to guess the TeXmacs installation prefix. If it gets this wrong, you can also set the make variable `tmdir` to point to your TeXmacs plugins directory. By default, the plugin files will be installed in the plugins/pure subdirectory of your system-wide TeXmacs directory, usually `/usr/local/share/TeXmacs` or similar. Removing the plugins/pure directory is sufficient to uninstall the plugin; you can also do this with `sudo make uninstall-tm`.

It’s also possible to disable the automatic installation by invoking configure with the `--without-texmacs` option. To do a manual installation, it should be sufficient to drop the texmacs/plugins/pure directory in the distribution into your personal TeXmacs plugins folder, usually `~/.TeXmacs/plugins`. You can also do this with `make install-tm tmdir=~/.TeXmacs` (in this case, uninstall with `make uninstall-tm tmdir=~/.TeXmacs`). This has the advantage that it doesn’t require root access and you can easily edit the plugin files under `~/.TeXmacs/plugins/pure/progs` afterwards to tailor them to your needs.

The distributed plugin has support for reading the Pure online help in TeXmacs format. See Step 6 under Basic Installation above for instructions on how you can obtain the necessary TeXmacs files and install them in the Pure library directory along with the html documentation. (The TeXmacs-formatted documentation needs a little style file named puredoc.ts which is included in the distribution and will be installed when doing `make install` or `make install-tm`. You can also just drop the file into your `~/.TeXmacs/packages` folder to make TeXmacs find it.)

If the distributed plugin doesn’t work for you, as a fallback option you can try the following minimal setup instead. This lacks all the bells and whistles of the distributed plugin, but should be sufficient to run a basic Pure session in TeXmacs, and should hopefully work with any TeXmacs version which has plugin support at all.

```
(plugin-configure pure
  (:require (url-exists-in-path? "pure"))
)
This Scheme file should go into ~/.TeXmacs/plugins/pure/progs/init-pure.scm. Note that both the -i and --texmacs options are required in the launch command to make this work (you might also want to add the -q option to suppress the signon message of the interpreter).

### 40.5 Installing an LLVM-capable C/C++ Compiler

As already mentioned above, we suggest that you also install a C/C++ compiler with an LLVM backend. clang, llvm-gcc as well as the dragonegg gcc plugin are all fully supported by Pure. (Nowadays, the LLVM project’s main focus is on clang, however; llvm-gcc and dragonegg are not supported on recent systems any more.) Pure can be used without this, but then you’ll miss out on the LLVM bitcode loader and C/C++ inlining facilities in Pure 0.44 and later. (Note that you can always install clang, llvm-gcc and/or dragonegg at a later time to enable these features.)

#### 40.5.1 clang

With LLVM 2.8 and later, we recommend installing clang, the new LLVM-based C/C++ compiler (http://clang.llvm.org/). It’s much easier to build, runs faster and has better diagnostics than gcc. Also, as of Pure 0.55 it is the default for compiling inline C/C++ code, so it’s the easiest way to go if you want to use that feature.

If you haven’t built clang along with LLVM yet, you can now just drop the contents of the clang tarball into the llvm/tools directory, renaming the resulting clang-x.y directory to just clang. Then build and install clang as follows:

```
$ cd llvm-3.4/tools/clang
$ make
$ sudo make install
```

#### 40.5.2 llvm-gcc

**Note:** LEGACY ALERT: This section applies to LLVM versions up to 2.9. With LLVM 3.0 or later, llvm-gcc is not supported any more and you should use clang instead.

If available, llvm-gcc can be installed either as an alternative or in addition to clang. The main advantage of llvm-gcc over clang is that it has additional language frontends (Ada and Fortran).

Installing llvm-gcc from source actually isn’t all that difficult, if a bit time-consuming. Assuming that you have unpacked both the LLVM and the llvm-gcc sources in the same directory, you can build and install llvm-gcc as follows:

```
$ cd llvm-gcc-4.2-2.9.source
$ mkdir obj
```
$ cd obj
$ ../configure --program-prefix=llvm- --enable-llvm=$PWD/../../llvm-2.9 --enable-languages=c,c++
$ make
$ sudo make install

(You might wish to add fortran to --enable-languages if you also want to build the Fortran compiler, and, likewise, ada for the Ada compiler.)

Be patient, this takes a while.

Having installed llvm-gcc, you can add something like the following lines to your shell startup files, so that Pure uses it for inlined C/C++/Fortran code:

```plaintext
echo "export PURE_CC=llvm-gcc"
echo "export PURE_CXX=llvm-g++"
echo "export PURE_FC=llvm-gfortran"
```

### 40.5.3 dragonegg

**Note:** LEGACY ALERT: This section applies to LLVM versions up to 3.3 and gcc 4.5 or 4.6. If you’re running a newer LLVM and/or gcc version, you should use clang instead.

Instead of llvm-gcc it’s also possible to use “DragonEgg” (http://dragonegg.llvm.org/). This is provided in the form of a gcc plugin which, if you have one of the supported gcc versions, readily plugs into your existing system compiler.

To install DragonEgg, make sure that you have the mpc and gcc plugin development files installed (packages mpc-dev and gcc-plugin-dev on Ubuntu). Then, after unpacking the dragonegg source tarball or downloading the svn sources, install dragonegg as follows:

```plaintext
$ make
$ sudo cp dragonegg.so `gcc -print-file-name=plugin`
```

Finally, add something like the following lines to your shell startup files, so that Pure uses gcc+dragonegg for all inlined C/C++/Fortran code:

```plaintext
export PURE_CC="gcc -fplugin=dragonegg"
export PURE_CXX="g++ -fplugin=dragonegg"
export PURE_FC="gfortran -fplugin=dragonegg"
```

(Please also check the README file included in the dragonegg package for further installation and usage instructions. Also, examples/bitcode/Makefile in the Pure distribution demonstrates how to use gcc+dragonegg as an external compiler to generate LLVM bitcode from the command line.)

### 40.6 Installing From Development Sources

The latest development version of Pure is available in its Git source code repository. You can browse the repository at:
https://github.com/agraef/pure-lang

(You’ll notice that the repository also contains various addon modules. See the pure subdirectory for the latest sources of the Pure interpreter itself.)

Note that if you’re going with the development sources, you’ll also need fairly recent versions of autoconf, flex and bison (autoconf 2.63, flex 2.5.31 and bison 2.3 or later should be ok).

To compile from the development sources, replace steps 4 and 5 above with:

**Step 4’.** Fetch the latest sources from the repository:

```bash
$ git clone https://github.com/agraef/pure-lang.git
```

This clones the repository and puts it into the pure-lang subdirectory in the current directory. This step needs to be done only once; once you’ve cloned the repository, you can update it to the latest revision at any time by running `git pull`.

**Step 5’.** Configure, build and install Pure.

This is pretty much the same as with the distribution tarball, except that you need to run `autoreconf` once to generate the configure script which isn’t included in the source repository.

```bash
$ cd pure-lang/pure
$ autoreconf
$ ./configure --enable-release
$ make
$ sudo make install
```

(Don’t forget to also run `make check` to make sure that the interpreter is in good working condition.)

**Step 6’.** In addition, you can also build and install a recent snapshot of the documentation from the repository.

This can be a bit tricky to set up, please check the FAQ wiki page on the Pure website for details.

Alternatively, a ready-made recent snapshot of the documentation in html and pdf formats is also available in its own repository, which can be cloned as follows:

```bash
$ git clone https://github.com/agraef/pure-docs.git
```

### 40.7 Other Build and Installation Options

The Pure configure script takes a few options which enable you to change the installation path and control a number of other build options. Moreover, there are some environment variables which also affect compilation and installation.

Use `./configure --help` to print a summary of the provided options.
40.7.1 Installation Path

By default, the pure program, the runtime.h header file, the runtime library, the pure.pc file and the library scripts are installed in /usr/local/bin, /usr/local/include/pure, /usr/local/lib, /usr/local/lib/pkg-config and /usr/local/lib/pure, respectively. This can be changed by specifying the desired installation prefix with the --prefix option, e.g.:

```
$ ./configure --enable-release --prefix=/usr
```

In addition, the DESTDIR variable enables package maintainers to install Pure into a special “staging” directory, so that installed files can be packaged more easily. If set at installation time, DESTDIR will be used as an additional prefix to all installation paths. For instance, the following command will put all installed files into the tmp-root subdirectory of the current directory:

```
$ make install DESTDIR=tmp-root
```

Note that if you install Pure into a non-standard location, you may have to set LD_LIBRARY_PATH or a similar variable so that the dynamic linker finds the Pure runtime library, libpure.so. Also, when compiling and linking addon modules you might have to set C_INCLUDE_PATH and LIBRARY_PATH (or similar) so that the header and library of the runtime library is found. (This will become unnecessary once all addon modules have been converted to use pkg-config, see below, but this isn’t the case right now.) On some systems this is even necessary with the default prefix, because /usr/local is not always in the default search paths.

As of Pure 0.47, Pure also installs a pkg-config file which may be queried by module Makefiles to determine how to build a module and link it against the Pure runtime library; see Pkgconfig Support below. This file will usually be installed into $(prefix)/lib/pkg-config. Again, if you use a non-standard installation prefix, you will have to tell pkg-config about the location of the file by adjusting the PKG_CONFIG_PATH environment variable accordingly, see pkg-config(1) for details.

40.7.2 Tool Prefix and LLVM Version

On some systems the LLVM toolchain may be located in special directories not on the PATH, so that different LLVM installations can coexist on the same system. This is often the case, e.g., if LLVM was installed from a binary package.

To deal with this situation, the configure script distributed with Pure 0.55 and later allows you to specify the directory with the LLVM toolchain using the --with-tool-prefix configure option. E.g.:

```
$ ./configure --with-tool-prefix=/usr/lib/llvm-3.4/bin
```

This is also the directory where configure will first look for the llvm-config script, so that the proper LLVM version is selected for compilation.

You can also specify the desired LLVM version with the --with-llvm-version option. This causes configure to look for the llvm-config-x.y script on the PATH, where x.y is the speci-
fied version number. If this option isn’t specified, the default is to look for the `llvm-config` script on the `PATH` (this should always work if you installed LLVM from source).

If none of these yield a usable `llvm-config` script, configure will try to locate an `llvm-config-x.y` script by iterating through some recent LLVM releases, preferring the latest version if found. If this fails, too, configure gives up and prints an error message indicating that it couldn’t locate a suitable LLVM installation. This is a fatal error, so if you see this then you’ll either have to install LLVM yourself, or try to locate a suitable LLVM installation and tell configure about it, using the options explained above.

### 40.7.3 Versioned Installations

Pure fully supports parallel installations of different versions of the interpreter. To enable this you have to specify `--enable-versioned` when running configure:

```
$ ./configure --enable-release --enable-versioned
```

When this option is enabled, `bin/pure`, `include/pure`, `lib/pure`, `lib/pkg-config/pure.pc` and `man/man1/pure.1` are actually symbolic links to the current version (`bin/pure-x.y`, `include/pure-x.y` etc., where `x.y` is the version number). If you install a new version of the interpreter, the old version remains available as `pure-x.y`.

Note that versioned and unversioned installations don’t mix very well, it’s either one or the other. If you already have an unversioned install of Pure, you must first remove it before switching to the versioned scheme.

It is possible, however, to have versioned and unversioned installations under different installation prefixes. For instance, having an unversioned install under `/usr` and several versioned installations under `/usr/local` is ok.

### 40.7.4 Separate Build Directory

It is possible to build Pure in a separate directory, in order to keep your source tree tidy and clean, or to build multiple versions of the interpreter with different compilation flags from the same source tree.

To these ends, just `cd` to the build directory and run configure and make there, e.g. (this assumes that you start from the source directory):

```
$ mkdir BUILD
$ cd BUILD
$ ../configure --enable-release
$ make
```

### 40.7.5 Compiler and Linker Options

There are a number of environment variables you can set on the configure command line if you need special compiler or linker options:

- `CPPFLAGS`: preprocessor options (`-I`, `-D`, etc.)
• CXXFLAGS: C++ compilation options (-g, -O, etc.)
• CFLAGS: C compilation options (-g, -O, etc.)
• LDFLAGS: linker flags (-s, -L, etc.)
• LIBS: additional objects and libraries (-lfoo, bar.o, etc.)

(The CFLAGS variable is only used to build the pure_main.o module which is linked into batch-compiled executables, see “Batch Compilation” in the manual for details.)

For instance, the following configure command changes the default compilation options to -g and adds /opt/include and /opt/lib to the include and library search paths, respectively:

```
$ ./configure CPPFLAGS=-I/opt/include CXXFLAGS=-g LDFLAGS=-L/opt/lib
```

More details on the build and installation process and other available targets and options can be found in the Makefile.

40.7.6 Predefined Build Types

For convenience, configure provides some options to set up CPPFLAGS and CXXFLAGS for various build types. Please note that most of these options assume gcc right now, so if you use another compiler you’ll probably have to set up compilation flags manually by using the variables described in the previous section instead.

The default build includes debugging information and additional runtime checks which provide diagnostics useful for maintainers if anything is wrong with the interpreter. It is also noticeably slower than the “release” build. If you want to enjoy maximum performance, you should configure Pure for a release build as follows:

```
$ ./configure --enable-release
```

This disables all runtime checks and debugging information in the interpreter, and uses a higher optimization level (-O3), making the interpreter go substantially faster on most systems.

To get smaller executables with either the default or the release build, add LDFLAGS=-s to the configure command (gcc only, other compilers may provide a similar flag or a separate command to strip compiled executables and libraries).

You can also do a “debug” build as follows:

```
$ ./configure --enable-debug
```

This is like the default build, but disables all optimizations, so compilation is faster but the compiled interpreter is much slower than even the default build. Hence this build is only recommended for debugging purposes.

You can combine all build types with the --enable-warnings option to enable compiler warnings (-Wall):
$ ./configure --enable-release --enable-warnings

This option is useful to check the interpreter sources for questionable constructs which might actually be bugs. However, for some older gcc versions it spits out lots of bogus warnings, so it is not enabled by default.

In addition, there is an option to build a “monolithic” interpreter which is linked statically instead of producing a separate runtime library:

$ ./configure --enable-release --disable-shared

We strongly discourage from using this option, since it drastically increases the size of the executable and thereby the memory footprint of the interpreter if several interpreter processes are running simultaneously. It also makes it impossible to use batch compilation and addon modules which require the runtime library. We only provide this as a workaround for older LLVM versions which cannot be linked into shared libraries on some systems.

In general, the build options can be combined freely with the variables described in the previous section, except that `--enable-release` and `--enable-debug` will always override the debugging (`-g`) and optimization (`-O`) options in `CFLAGS` and `CXXFLAGS`. Other options will be preserved. For instance, the following configures for a release build, but sets the warning flags manually and enables C++0x support in gcc:

$ ./configure --enable-release CFLAGS="-Wall" CXXFLAGS="-std=c++0x -Wall"

If you mix build types and manual compilation flags in this way then it’s always a good idea to check the resulting compilation options printed out at the end of the `configure` run. If `configure` seems to get things wrong then you’ll have to set up all required flags manually instead.

### 40.7.7 Running Pure From The Source Directory

After your build is done, you should also run `make check` to verify that your Pure interpreter works correctly. This can be done without installing the software. In fact, there’s no need to install the interpreter at all if you just want to take it for a test drive, you can simply run it from the source directory, if you set up the following environment variables (this assumes that you built Pure in the source directory; when using a separate build directory, you’ll have to change the paths accordingly):

`LD_LIBRARY_PATH=.`. This is required on Linux systems so that libpure.so is found. Other systems may require an analogous setting, or none at all.

`PURELIB=./lib` This is required on all systems so that the interpreter finds the prelude and other library scripts.

After that you should be able to run the Pure interpreter from the source directory, by typing `./pure`. 

---

**40.7 Other Build and Installation Options**
40.7.8 Other Targets

The Makefile supports the usual clean and distclean targets, and realclean will remove all files created by the maintainer, including test logs and C++ source files generated from Flex and Bison grammars. (Only use the latter if you know what you are doing, since it will remove files which require special tools to be regenerated.)

Maintainers can roll distribution tarballs with make dist and make distcheck (the latter is like make dist, but also does a test build and installation to verify that your tarball contains all needed bits and pieces).

Last but not least, if you modify configure.ac for some reason then you can regenerate the configure script and config.h.in with make config. This needs autoconf, of course. (The distribution was prepared using autoconf 2.69.)

40.7.9 Pkg-config Support

Pure 0.47 and later install a pkg-config file (pure.pc) which lets addon modules query the installed Pure for the information needed to build and install a module. Besides the usual information provided by pkg-config, such as --cflags and --libs (which are set up so that the Pure runtime header and library will be found), pure.pc also defines a few additional variables which can be queried with pkg-config's --variable option:

- DLL: shared library extension for the host platform
- PIC: position-independent code flag if required on the host platform
- shared: flag used to create shared libraries on the host platform
- extraflags: same as $shared $PIC

Together with the libdir variable, this provides you with the information needed to build and install most Pure modules without much ado. As of Pure 0.55, pure.pc also defines the tool_prefix variable which gives the LLVM toolchain prefix specified at configure time, cf. Tool Prefix and LLVM Version.

If you want to use this information, you need to have pkg-config installed, see http://pkg-config.freedesktop.org. This program should be readily available on most Unix-like platforms, and a Windows version is available as well. An example illustrating the use of pkg-config can be found in the examples/hellomod directory in the sources.

40.8 System Notes

Pure is known to work on recent Linux, Mac OS X and BSD versions under x86, x86-64 (AMD/Intel x86, 32 and 64 bit) and ppc (PowerPC), as well as on MS Windows (AMD/Intel x86, 32 bit). There are a few known quirks for specific platforms and/or LLVM versions which are discussed below, along with corresponding workarounds. As a fairly demanding LLVM application, Pure is also known to shake the bugs out of LLVM, so if you run into any LLVM-related issues, Pure isn’t necessarily the culprit! However, most of the bugs have been ironed out over the years, so Pure should work fine with any recent LLVM version (3.4 or later).
40.8.1 All Platforms

Compiling the default and release versions using gcc with all warnings turned on (`-Wall`) might give you the warning “dereferencing type-punned pointer will break strict-aliasing rules” at some point in util.cc with some older gcc versions. This is harmless and can be ignored.

If your Pure program runs out of stack space, the interpreter may segfault. While the Pure interpreter does advisory stack checks to avoid that kind of mishap and generate an orderly exception instead, it has no way of knowing the actual stack size available to programs on your system. So if you’re getting segfaults due to stack overflows then you’ll have to set an appropriate stack size limit manually with the `PURE_STACK` environment variable; see the Pure manual for details.

40.8.2 LLVM 2.5

The LLVM 2.5 JIT is broken on x86-32 if it is built with `-enable-pic`, so make sure you do not use this option when compiling LLVM <=2.5 on 32 bit systems. On the other hand, building the Pure runtime library (libpure) on x86-64 systems requires that you configure LLVM 2.5 with `-enable-pic` so that the static LLVM libraries can be linked into the runtime library. With LLVM 2.6 and later, this option isn’t needed anymore.

This LLVM version also has issues on PowerPC. Use LLVM 2.6 or later instead and check the notes on PowerPC below.

Please also note that LLVM 2.5 is the oldest LLVM version that we still support right now. If you’re still running this version (or any of the 2.x versions) then you should really upgrade. Newer LLVM versions offer substantial improvements in both compilation time and code quality. Support for LLVM versions older than 3.0 is likely to be dropped in future Pure releases.

40.8.3 LLVM 3.3

Reportedly the Pure batch compiler is broken when using LLVM 3.3 on Mac OS X. If you need the batch compiler then use either LLVM 3.2 or 3.4+ on OS X instead, these are known to work on that platform.

40.8.4 LLVM 3.4+

On Linux, the `llc` program from LLVM 3.4 and 3.5 is known to create native assembler (.s) code which doesn’t mangle assembler symbols as it used to be in earlier releases. When compiling Pure modules with the batch compiler, this results in native assembler code which can’t be compiled using the system assemblers. As a remedy, the batch compiler in Pure 0.61 and later now creates native object (.o) files directly using `llc`, without going through the native assembler stage.
40.8.5 LLVM 3.6+

Pure doesn’t work with LLVM versions 3.6 and beyond yet because these don’t include the “old” LLVM JIT any more. So until Pure gets ported to the new MCJIT, you will have to stick with LLVM 3.5. Fortunately, this version is still readily available on most platforms.

40.8.6 PowerPC

(This hasn’t been checked in a long time, so this information may well be outdated.) You’ll need Pure >= 0.35 and LLVM >= 2.6. Also make sure that you always configure LLVM with --disable-expensive-checks and Pure with --disable-fastcc. With these settings Pure should work fine on ppc (tested on ppc32 running Fedora Core 11 and 12), but note that tail call optimization doesn’t work on this platform because of LLVM limitations.

40.8.7 Linux

Linux is the primary development platform for this software, and the sources should build out of the box on all recent Linux distributions. Packages for various Linux distributions are also available, please check the Pure website for details.

40.8.8 Mac OS X

Pure should build fine on recent OS X versions, and a port by Ryan Schmidt exists in the MacPorts collection, see http://www.macports.org/. If you install straight from the source, make sure that you use a recent LLVM version (LLVM 2.7 or later should work fine on all flavors of Intel Macs).

Even if you compile Pure from source, we recommend installing LLVM and the other dependencies from MacPorts. In that case you’ll have to add a few options to the configure command so that the required header files, libraries and LLVM tools are found:

```
./configure --enable-release --prefix=/opt/local \
CPPFLAGS=-I/opt/local/include LDFLAGS=-L/opt/local/lib \
--with-tool-prefix=/opt/local/libexec/llvm-3.4/bin
```

This assumes that your MacPorts installation lives under /opt/local and that you’re using LLVM 3.4; otherwise you’ll have to adjust the configure options accordingly.

On really old Macs from the bygone PPC era you’ll have to be prepared to deal with all kinds of issues with compilers, LLVM toolchain etc. If you’re still using one of these, your best bet is to find an older port on MacPorts which works for your OS X version.

40.8.9 BSD

FreeBSD now offers a fairly extensive selection of Pure packages in their distribution. Compilation from source should also work fine on recent NetBSD and FreeBSD versions if you use Pure 0.33 or later. Also make sure that you install a recent port of LLVM which has the --enable-optimized flag enabled.
Building Pure requires GNU make, thus you will have to use gmake instead of make. In addition to gmake, you’ll need recent versions of the following packages: perl5, flex, bison, gmp, mpfr and readline (or editline). Depending on your system, you might also have to set up some compiler and linker paths. E.g., the following reportedly does the trick on NetBSD:

```bash
export C_INCLUDE_PATH=/usr/local/include:/usr/pkg/include
export LIBRARY_PATH=/usr/local/lib:/usr/pkg/lib
export LD_LIBRARY_PATH=/usr/pkg/lib:/usr/local/lib
```

### 40.8.10 MS Windows

Thanks to Jiri Spitz’ perseverance, tireless testing and bug reports, the sources compile and run fine on Windows, using the Mingw port of the GNU C++ compiler and the MSYS environment from [http://www.mingw.org/](http://www.mingw.org/). Just do the usual `./configure && make && make install`. You’ll need LLVM, of course (which builds with Mingw just fine), and a few additional libraries for which headers and precompiled binaries are available from the Pure website ([https://agraef.github.io/pure-lang/](https://agraef.github.io/pure-lang/)).

However, the easiest way is to just go with the Pure MSI package available on the Pure website. This includes all required libraries and some shortcuts to run the Pure interpreter and read online documentation in html help format, as well as “PurePad”, an alternative GUI frontend for editing and running Pure scripts on Windows. The only limitation is that the binaries in this package still are for x86 (32 bit) only right now, but these do work fine on all recent 64 bit flavors of Windows (tested on Windows 7, 8 and 10).
Chapter 41

Reporting Bugs

Pure is still under development, but the language and its standard library are fairly stable and mature. If you find a bug or other deficiency in either the documentation, the Pure interpreter or one of the library modules, we would like to know about it. You can submit bug reports at the Pure issue tracker which is available here:

https://github.com/agraef/pure-lang/issues

If you are unsure if the problem you are hitting is really a bug, or if you’d like to discuss possible enhancements and other kinds of fixes, then you might consider posting to the Pure mailing list at Google Groups:

http://groups.google.com/group/pure-lang

Some issues are best discussed interactively. For these purposes we also have an IRC chat at Freenode (archived here):

irc://irc.freenode.net/pure-lang
